Abstract

A detailed experimental study of a hybrid composite system for thermal management (TM) of electronics devices was performed. Three different TM modules made of pure carbon foam (CF), a composite of CF and Paraffin wax (RT65) as a phase change material (PCM), and a composite of CF, RT65 and multi wall carbon nanotubes (MWCNTs) as a thermal conductivity enhancer were developed and tested. Two types of carbon foam materials of different thermal conductivities, namely CF-20 of low thermal conductivity (3.1 W/m K) and KL1-250 of medium thermal conductivity (40 W/m K) were used in the three Modules. Tests conducted at different power densities showed a reasonable delay in reaching the heater steady state temperatures using TM module made of CF + RT65 as compared to pure CF. Heat transfer enhancement due to entrapped MWCNTs in the CF micro cells have a significant effect on the thermal response of the TM modules. The delay and decrease of heater surface temperature increase with the inclusion of MWCNTs in the TM module made of CF + RT65/MWCNTs. TM modules with enhanced thermal conductivity of carbon foam KL1-250 was shown to have good capability to control a high power loads as compared to CF-20. The effectiveness of inclusion of MWCNTs was remarkable in TM modules based on CF-20 as compared to KL1-250. © 2014 Elsevier Masson SAS. All rights reserved.

Abstract

Context. Toxicity from recreational substances marketed for other purposes is a well-documented clinical entity. We present two cases of phenibut toxicity procured via the internet. Case Details. A 20-year-old female presented to the emergency department (ED) having used phenibut the prior day. The main finding was a decreased level of consciousness, however when roused she became delirious. Supportive care only was required with no specific intervention. The patient made a full recovery over a 24-hour period and admitted to use of phenibut purchased online. Plasma phenibut concentration was 29.7 µg/ml. A 38-year-old male presented to ED with an agitated delirium. The prior evening he had used tetrahydrocannabinol or THC, alcohol and phenibut, the latter purchased via the internet. His behavioural state had a suboptimal response to parenteral sedation. He was subsequently intubated for airway protection in the context of ongoing sedation to optimally manage his behavioural state. Post extubation the next morning he admitted using phenibut. Plasma phenibut concentration was 36.5 µg/ml. Discussion. Altered mental status was the predominant manifestation of phenibut toxicity in these cases. Clinicians to be aware of how phenibut

toxicity may present as the internet has widened access to such substances. © 2015 Informa Healthcare USA, Inc.

^c Chemistry Department, Faculty of Science, Helwan University, Cairo, Egypt

Abstract

The rosin as natural product became a source for production of eco-friendly bio-surfactants which widely used in environmental protection issues. In this respect, nonionic surfactant was prepared from reaction of rosin maleic anhydride acid chloride with triethylene tetramine followed by etherification with poly (ethylene glycol) 600 to produce etherified rosin imide (ERIT-PEG) surfactant. The surface activity parameters of the prepared surfactant such as surface excess concentration (Tmax), the area per molecule at interface (Amin), and the effectiveness of surface tension reduction were measured in aqueous and 1M HCl solutions to determine the micellization and adsorption characteristics of the prepared surfactants at water/air interface. The inhibition effects of the etherified rosin imide (ERIT-PEG) surfactant on the corrosion of steel in 1 M HCl solution was studied by potentiodynamic polarization curves and electrochemical impedance spectroscopy (EIS). Inhibition efficiency (%IE) increased with increasing inhibitor concentration. Etherified rosin imide (ERIT-PEG) surfactants as a mixed-type inhibitor with a capability of blocking both anodic and cathodic sites on the steel surface immersed in 1M HCl. The inhibition efficiencies calculated from EIS are in good agreement with those obtained from potentiodynamic polarization. © 2015 The Authors.

Abstract

Parasitic diseases differ in prevalence, course, and severity between males and females. The study was designed to compare males with females for the susceptibility to *Eimeria papillata* infection as well as the expression of the mucin gene, MUC2. Oocysts output was detected to be more in the feces of male mice ($3.5 \times 10^4 \pm 4000$ oocysts/g feces) than in females ($2 \times 10^4 \pm 2000$ oocysts/g feces). In addition, infected males showed a significant higher number of meronts, gamonts, and developing oocysts compared to infected female mice. Moreover, *E. papillata* induced a marked goblet cell hypoplasia where the jejunum of infected male mice contained lower numbers of goblet cells per ten villus-crypt units compared to infected females. Also, the expression of MUC2 mRNA is found to be more expressed in infected females than males. In addition, testosterone, nitric oxide, and inducible nitric oxide synthase activities were found to be higher in infected male mice than in infected females. In general, male Swiss albino mice have been shown to be relatively more susceptible to infection with *E. papillata* when compared with female mice. © 2014, Springer-Verlag Berlin Heidelberg.

Abstract

Ionic liquids (ILs) attracted great attention as green corrosion inhibitors for steel in aggressive environments. The present work synthesize new IL using chitosan through amidation and quaternization reaction with oleic acid and p-toluene sulfonic acid, respectively. The chemical structure of the prepared polymeric ionic liquid was investigated using NMR analysis. The corrosion inhibitive effect of the prepared polymeric ionic liquid on steel corrosion in acid chloride solution was studied using different electrochemical techniques. Potentiodynamic polarization data revealed that the prepared ionic liquid reduces both dissolution and hydrogen evolution corrosion reactions. Impedance technique shows one capacitive loop that indicated the charge-transfer process of the steel corrosion. Langmuir isotherms found to fit properly the adsorption of the prepared polymeric ionic liquid over the steel surfaces. © 2015 The Authors.

Effect of poisson's ratio on stress/strain concentration at circular holes in elastic plates subjected to biaxial loading- Three dimensional finite element analysis

(2015) *Proceedings of the 24th International Mining Congress of Turkey, IMCET 2015*, pp. 481-487.

^a Mechanical Engineering Dept., Faculty of Engineering, Helwan University, Jazan 706, Cairo, Egypt

^b Mining Engineering Department, Faculty of Engineering, King Abdulaziz University, Jeddah, Saudi Arabia

Abstract

The influence of Poisson's ratio (ν) on stress and strain concentration factors of plate contains a circular notch and subjects to biaxial loading have been systematically analyzed by using three dimensional finite element (3DFE) method. It is necessary to determine stress and strain concentration factors around the circular notch in order to determine the site of crack initiation. The numerical results of the stress and strain concentration factors are traced through the plate thickness. A plate under elastic state has been used in the present work. Four values of Poisson's ratio (ν) were studied numerically, varied from 0.1 to 0.4. It is found that the maximum stress and strain concentration factors increase with increasing the Poisson's ratio (ν). The stress and strain concentration factors increase with decrease the biaxial ratio. Furthermore, the effect of Poisson's ratio (ν) on stress and strain concentration factor decreases with increasing the biaxial ratio.

Abstract

Malva parviflora (little mallow) is a wild herb with agricultural importance in Egypt, where it is cultivated as a food crop. The main objective of the present work was to study the distribution and common associated species of the arable weed, *M.parviflora*, in the Nile Delta, Egypt. In addition, the diversity and behavior of the common species along the prevailing environmental conditions were assessed. Fifty stands, representing five common habitats (crop fields, orchards, canals, drains and roadsides), were selected. Eighty-five species and one variety (50 annuals and 36 perennials) were recorded. Therophytes dominated the other life forms and biregional taxa contributed the highest chorological elements. *Malva parviflora* is a therophytic plant that has a Mediterranean distribution intermingled with Irano-Turanian elements. Moreover, the highest coverage percentage of *M.parviflora* was recorded in the canal banks. Four vegetation groups that represented the distinct habitats were produced by the application of a two-way indicator species analysis and a detrended correspondence analysis as a classification and ordination technique, respectively. Vegetation group C, which inhabited the crop fields, was the most diverse. A canonical correspondence analysis indicated that calcium carbonate, organic carbon, carbonate, potassium and the potassium adsorption ratio and electrical conductivity are the most effective soil variables on the distribution of *M.parviflora* and its associated species in the different habitats. It was found that *M.parviflora* was affected greatly by calcium carbonate, sand and magnesium. In addition, it was significantly associated with soil bicarbonate. Such a study could help in managing this important agricultural weed. © 2014 Weed Science Society of Japan.

Abstract

Non-uniqueness of satellite gravity interpretation has traditionally been reduced by using a priori information from seismic tomography models. This reduction in the non-uniqueness has been based on velocity-density conversion formulas or user interpretation of the 3D subsurface structures (objects) based on the seismic tomography models and then forward modelling these objects. However, this form of object-based approach has been done without a standardized methodology on how to extract the sub-surface structures from the 3D models. In this research, a 3D object-oriented image analysis (3D OOA) approach was implemented to extract the 3D subsurface structures from geophysical data. The approach was applied on a 3D shear wave seismic tomography model of the central part of the East African Rift System. Subsequently, the extracted 3D objects from the tomography model were reconstructed in the 3D interactive modelling environment IGMAS+, and their density contrast values were calculated using an object-based inversion technique to calculate the forward signal of the objects and compare it with the measured satellite gravity. Thus, a new object-based approach was implemented to interpret and extract the 3D subsurface objects from 3D geophysical data. We also introduce a new approach to constrain the interpretation of the satellite gravity measurements that can be applied using any 3D geophysical model. © 2013 Elsevier B.V.

Fabrication of PtNi bimetallic nanoparticles supported on multi-walled carbon nanotubes

(2015) *Journal of Experimental Nanoscience*, 10 (5), pp. 392-406. Cited 1 time.

DOI: 10.1080/17458080.2013.838703

^b Graduate Institute of Applied Science and Technology, Honors College, National Taiwan University of Science and Technology, Taipei, Taiwan

Abstract

Platinum/nickel bimetallic nanoparticles supported on multi-walled carbon nanotubes (x PtNi/CNTs) were synthesised. The fabrication process includes the chemical modification on the graphene surface of CNTs by acid treatment and the subsequent deposition of Pt or PtNi bimetallic nanoparticles with different compositions of Pt ($x = 100, 90, 80$ and 70 wt%). The deposition was carried out using ethylene glycol as a reducing agent in the polyol method or using poly(amidoamine) dendrimer as a platform and sodium borohydride as a reducing agent to load the metal nanoparticles on the CNT surface. The structures of the produced PtNi/CNT nanoparticles were investigated by ultraviolet absorption spectra, X-ray diffraction (XRD) and the composite ratio consisting of 70 wt% of metal content and 30 wt% of CNTs was confirmed by the thermogravimetric analysis. The morphology and the phase identification of the produced PtNi/CNT nanoparticles were investigated by high-resolution scanning electron microscope, transmission electron microscope and XRD measurements. It was observed that the deposited Pt and PtNi bimetallic nanoparticles on the surface of CNTs had average particle sizes of $2\text{--}16$ nm, when they were prepared from the polyol method. On the other hand, the PtNi/CNT nanoparticles prepared by using a dendrimer as an intermediate had a smaller particle size and more uniform size distribution of the quantum dot size ranged from 2 to 4 nm. © 2013, © 2013 Taylor & Francis.

Abstract

In the present study, new magnetite nanoparticles coated with rosin amidoxime prepared to apply as corrosion inhibitors for steel in 1 M HCl. Rosin midoxime was prepared from hydrolysis of rosin-acrylonitrile Diels Alder adduct using hydroxylamine in basic medium. A new monodisperse magnetite nanoparticles was prepared by a simple and inexpensive co-precipitation method followed by capping with rosin amidoxime. The chemical structure, particle size and morphology of magnetite capped with rosin amidoxime were characterized by Fourier transform infrared spectroscopy (FTIR), transmission electron microscopy (TEM), and dynamic light scattering (DLS). Corrosion protection properties of magnetite-RK/amidoxime nanoparticles on steel in hydrochloric acid have been studied by polarization and electrochemical impedance spectroscopy (EIS). The results show that magnetite-RK/amidoxime nanoparticles acts as good inhibitor and inhibition efficiency (%IE) increases with inhibitor concentration. Potentiodynamic polarization measurements indicated that magnetite-RK/amidoxime nanoparticles acts as a mixed type inhibitor. EIS results indicated that the charge transfer resistance (R_{ct}) increases with magnetite-RK/amidoxime concentration. IE values obtained from potentiodynamic polarization showed a reasonable agreement with those obtained from EIS measurements. © 2015 The Authors.

Comparison between physical properties of ring-spun yarn and compact yarns spun from different pneumatic compacting systems

(2015) *Indian Journal of Fibre and Textile Research*, 40 (1), pp. 43-50.

^a Textile Research Division, National Research Center, Dokki, Cairo, Egypt

^b Helwan University, Helwan, Egypt

Abstract

A comparative study pertaining to physical and mechanical properties of ring-spun yarn vis-à-vis compact yarns spun using three different compacting systems has been reported. Rieter (K-44), Toyota (RX-240) and Suessen (Fiomax) spinning machines have been used and the condensing process of the fibres in the yarn cross-section as per these compact spinning systems is accomplished pneumatically. Thus, a yarn of linear density 5.9 tex (100 Ne) is spun on the spinning systems using Egyptian cotton of the type Giza 86. One way Anova together with least significant difference are employed to feature the means of the properties of spun yarns and a significant difference among them is observed. According to the performed statistical analysis, there is a significant difference between ring - spun yarn properties and each of the pneumatic compact spun yarns. These compact-spun yarns are also found to differ significantly in terms of their physical and mechanical properties; however, they are all found superior to the ring-spun yarn. © 2015 National Institute of Science Communication and Information Resources (NISCAIR). Abstract

Background/aim: To date, liver biopsy has been the gold standard used for the assessment of liver fibrosis in patients with chronic hepatitis C. Our aim was to evaluate the diagnostic performance of a panel of simple blood markers of liver fibrosis and the development a novel score to replace liver biopsy. **Patients and methods:** Liver biochemical profile including transaminases, bilirubin, alkaline phosphatase, and albumin, in addition to platelet count, was evaluated using standard methods in 305 chronic hepatitis C patients. Serum type IV collagen and laminin were assayed using the ELISA technique. Liver biopsies were performed. Statistical analyses were carried out by logistic regression and receiver operating characteristic curves to assess and compare the diagnostic accuracy of blood markers. A stepwise combination algorithm was developed and validated in 317 additional patients. **Results:** The Fibrosis Discriminant Score (FDS) was developed combining collagen, laminin, aspartate aminotransferase/platelet ratio index, and albumin. FDS produced an area under receiver operating characteristic curve of 0.831 for significant fibrosis, 0.791 for advanced fibrosis, and 0.881 for cirrhosis. The FDS was correctly classified in 82% of patients with significant fibrosis with 79% sensitivity and 88% specificity at cut-off 0.66 or more. Similar results were obtained in a validation study in which, of 317 patients, liver biopsy could have been avoided in 81%. **Conclusion:** A simple fibrosis index can be useful to select hepatitis C virus-infected patients with a very low risk of significant fibrosis in whom the protocol of liver biopsies may be avoided. Comparative study of voltage stability analysis for renewable energy grid-connected systems using PSS/E

(2015) *Conference Proceedings - IEEE SOUTHEASTCON*, 2015-June (June), art. no. 7133012, .

DOI: 10.1109/SECON.2015.7133012

Department of Electrical Power and Machines, Helwan University, P.O. Box 11792, Helwan, Egypt

Abstract

The voltage stability of large scale renewable energy grid-connected system plays a major role in a power system

environment. Nowadays, Integration of large scale wind power may have severe impacts on the power system operation. Stable, reliable and economic operation of the power system under the massive integration of wind power is a big challenge to power system operators. This paper seeks to study the voltage stability problems for the integration of wind power and Photovoltaic (PV) to the IEEE-14 bus network. Modern analytical tools are demonstrated to study voltage stability analysis by using PV analysis and dynamic analysis. Comparative study is developed to present the behavior of voltage stability of the system that employs PV and different types of wind farms. These analyses define the amount of reactive power required to enhance voltage stability. Simulation of 14-IEEE network with integrated renewable energy sources is developed using PSS/E. © 2015 IEEE.

Abstract

6-Amino-2-thiouracil (1) was condensed with benzenesulfonyl chloride and p-toluenesulfonyl chloride in presence of pyridine as an acid binder to give sulfonamides 2a, b, which could be methylated in basic medium to give methylmercapto derivatives 3a, b, which in turn reacted with bromine in glacial acetic acid to yield 5-bromo derivatives 4a, b. On the other hand, compounds 2a, b were cyclocondensed with monochloroacetyl chloride, p-tolualdehyde in glacial acetic acid/pyridine, and ethyl bromoacetate to give the corresponding thiazolopyrimidines 5a, b, 6a, b, and 7a, b, respectively; also compounds 2a, b were hydrazinolyzed to compounds 8a, b, which could be cyclized to triazolopyrimidines 9a, b in presence of formic acid. They could also be condensed with p-anisaldehyde to give hydrazones 10a, b. In another pathway, compounds 2a, b were reacted with monochloroacetic acid in basic medium to give acetic acid derivatives 11a, b. It can be deduced from the preliminary screening results that the cell lines most sensitive to the antiproliferative activity of tested compounds are human liver HEPG2 and colon cancer HT-29. All selected compounds exhibited moderate to strong growth inhibition activity against the HEPG2 cell line with 50 % inhibitory concentration (IC₅₀) ranging between 1 and 10 µg/ml. The most active compounds, which revealed antiproliferative activity also against human colon HT-29 and breast MCF-7 cell lines, were 3a, 3b, 4a, and 10a. © 2013 The Author(s).

Abstract

Low stability in oil media and the hydrophobicity problems of the polysulfone electrospun membranes could be overcome in the present study. Synthesis of super-hydrophilic and highly stable in oil polysulfone electrospun nanofiber membrane was achieved by electrospinning of polysulfone solution containing NaOH nanoparticles followed by activation of the dried electrospun membrane by deposition of polyamide layer on the surface using m-phenylenediamine and 1,3,5-benzenetricarbonyl chloride. The introduced membrane has super-hydrophilicity characteristic (contact angle=30°), excellent stability in oil media and distinct performance in oil-water separation process. © 2014 Elsevier B.V. Abstract

Key message: This review article contributes in more understanding of most aspects of Calotropis procera biology and extend our knowledge about its behavior. Calotropis procera (Aiton) W.T (Asclepiadaceae) (Giant milkweed) is a xerophytic perennial shrub or small tree. It is native to tropical and subtropical Africa, Asia and common in the Middle East. It grows on a variety of soils, from fine to coarse texture, with varying degrees of salinity. The importance of C. procera in the functioning of ecosystems is reflected in its hosting of butterflies, while it also acts as a food plant for arthropods. In addition, it is used for medicinal purposes in many arid countries. Potential new uses of this species in semi-arid regions include the phytoremediation of soils contaminated with trace elements and the use of biomass as a source of renewable energy. © 2015, Springer-Verlag Berlin Heidelberg.

Abstract

Abstract: The adsorption of nickel (II) from aqueous solution onto different particle sizes of water-cooled blast furnace slag (WCBFS) was investigated. Batch experiments were performed to study the effect of contact time, initial concentration of nickel ions, initial pH of the solution, and temperature. The data was fitted to Langmuir and Freundlich isotherm models. The results showed that the Langmuir model better fitted the data obtained for the large-sized particles, while that for the finer-sized particles followed the Freundlich model best. Overall, the process was

considered a second-order reaction which involved some degree of intraparticle diffusion. The calculated energy of activation indicated that it was a chemisorption process for both fine- and coarse-sized particles. In conclusion, the finest WCBFS particle size (0.3 mm) showed a good potential as an adsorbent to remove this divalent metal ions from solution. © 2014, © 2014 Balaban Desalination Publications. Abstract

The electron density integral along the paths between a GPS satellite and receiver is known as Total Electron Content (TEC), and this parameter is used in studying the ionosphere behaviors. TEC can be obtained by means of many methods. A space-based radio navigation system, such as Global Positioning System (GPS), offers good opportunities for studying the ionosphere. The TEC is calculated from the group path delay and phase advance in GPS satellite signals along the slant paths connecting GPS receivers and satellites at 22,000 km. Locally, a dual frequency GPS receiver was installed in Helwan, Egypt (29.86°N, 31.32°E) in November 2009. Here, GPS data were analyzed to establish a daily observation of Vertical TEC in a region located near to the northern crest of the ionospheric equatorial anomaly. During a moderate geomagnetic storm, observed on 02-05 May 2010, a number of ionospheric/magnetic phenomena were observed. Also, observations for Pc5/Pi2 pulsations were recorded during the geomagnetic storm phases. These geomagnetic observations are taken from MAGDAS-magnetometer station, located at Aswan (23.59°N, 32.51°E). More than 10 TECU increase in the ionospheric TEC values were recorded during the daytime of 02 May, followed by a large reduction during 03 May, reference to the pre-storm conditions. This confirms the enhancement in the geomagnetic H-component peak during the storm's initial phase and its reduction during the main phase. © 2015 COSPAR.

Abstract

Electrospinning technique was used for the fabrication of Polycaprolactone (PCL) nanofibrous scaffolds as 2D

biodegradable polymer for soft and hard tissue replacement. Nanofiber's morphology, porosity, phase identification as well as thermal and biological properties were assessed using standard techniques. Bone marrow mesenchymal stem cells (BMSCs-hTERT) were used for investigating properties of PCL scaffolds in the field of tissue engineering. The ability of PCL nanofibrous scaffolds to attach, grow and differentiate the hBMSCs into matrix mineralizing osteoblastic cells was investigated. The SEM micrographs showed beads free and non-agglomerated highly aligned nanofibrous morphology with uniform diameter varied from 200 to 1000 nm depending on the solution concentration and voltage. The EDS results showed that the carbon is the principal element of PCL nanofibers indicating that there are no chemical impurities into PCL polymer. The results of DSC confirmed the semi-crystalline nature of PLC. The TGA results showed that the PCL nanofibers have single stage thermal degradation with no weight loss up to 220 °C, with a slight weight loss from 240-440 °C due to the combustion of organic PCL matrix. The cell culture results showed that the cells do attach to the scaffold and they are alive and proliferate in the same rate as when cultured on plastic. Moreover the human MSCs differentiated to osteoblasts with calcium deposition when cultured on PCL nanofibrous scaffold, this was confirmed by ALP-, Alezarin staining and by scanning electron microscopy. © 2015 by American Scientific Publishers.

Abstract

Nanostructured composites increase their sensitivity and performance when employed as material in corrosive environments. In the present study, poly(2-acrylamido-2-methyl-1-propane-sulfonic acid -co-N-isopropylacrylamide) hydrogels, were synthesized by free-radical crosslinking solution polymerization with different ratios of monomers to form colloidal hydrogels shell around poly(vinyl alcohol) core through epichlorohydrine, in order to obtain well-defined PVA(AMPS-NIPAm) core/shell nanogels with diameter nearly 30nm, which characterized by Fourier transform infrared spectroscopy (FTIR), transmission electron microscopy (TEM) and dynamic light scattering (DLS). The inhibition effect of PVA-NIPAm/AMPS nanogel on the corrosion of steel in 1.0 M HCl solution was studied by potentiodynamic polarization curves and electrochemical impedance spectroscopy (EIS). Potentiodynamic polarization studies indicate that the new PVA-NIPAm/AMPS nanogel is a mixed inhibitor. Impedance studies show that a protective film is formed on the steel surface in the presence of the inhibitor and exhibit its protective nature even at low concentration. The results of polarization measurements are in good agreement with those obtained from EIS data for acting PVA-NIPAm/AMPS nanogel as an efficient corrosion inhibitor in 1 M HCl. © 2015 The Authors.

Fault Diagnosis of Rolling Bearing Based on Time Waveform Analysis

(2015) SAE Technical Papers, 2015-April (April), .

DOI: 10.4271/2015-01-1671

^a Czech Technical University, Helwan University, Prague, Czech Republic

^b Faculty of Engineering, Helwan University, Cairo, Egypt

Abstract

In this paper, a fault in rolling bearing is diagnosed using time waveform analysis. In order to verify the ability of time waveform analysis in fault diagnosis of rolling bearing, an artificial fault is introduced in vehicle gearbox bearing: an orthogonal placed groove on the inner race with the initial width of 0.6 mm approximately. The faulted bearing is a roller bearing located on the gearbox input shaft - on the clutch side. An optimal Morlet Wavelet Filter and autocorrelation enhancement are applied in this paper. First, to eliminate the frequency associated with interferential vibrations, the vibration signal is filtered with a band-pass filter determined by a Morlet wavelet whose parameters are optimized based on maximum Kurtosis. Then, to further reduce the residual in-band noise and highlight the periodic impulsive feature, autocorrelation enhancement is applied to the filtered signal. The proposed techniques are used respectively to analyze the experimental signal of vehicle gearbox rolling bearing. The test stand is equipped with two dynamometers; the input dynamometer serves as internal combustion engine, the output dynamometer introduce the load on the flange of output joint shaft. Gear Fault Diagnosis Based on Optimal Morlet Wavelet Filter and Autocorrelation Enhancement

(2015) SAE Technical Papers, 2015-April (April), .

DOI: 10.4271/2015-01-0212

Abstract

An efficient condition monitoring system provides early warning of faults by predicting them at an early stage. When a localized fault occurs in gears, the vibration signals always exhibit non-stationary behavior. The periodic impulsive feature of the vibration signal appears in the time domain and the corresponding gear mesh frequency (GMF) emerges in the frequency domain. However, one limitation of frequency-domain analysis is its inability to handle non-stationary waveform signals, which are very common when machinery faults occur. Particularly at the early stage of gear failure, the GMF contains very little energy and is often overwhelmed by noise and higher-level macro-structural vibrations. An effective signal processing method would be necessary to remove such corrupting noise and interference. In this paper, a new hybrid method based on optimal Morlet wavelet filter and autocorrelation enhancement is presented. First, to eliminate the frequency associated with interferential vibrations, the vibration signal is filtered with a band-pass filter determined by a Morlet wavelet whose parameters are selected or optimized based on maximum Kurtosis. Then, to further reduce the residual in-band noise and highlight the periodic impulsive feature, an autocorrelation enhancement algorithm is applied to the filtered signal. The pitting defect is manufactured on the tooth side of a gear of the fifth speed on the secondary shaft. The gearbox used for experimental measurements is of the type most commonly used in modern small to mid-sized passenger cars. The results show the ability of the proposed method to enhance the capability of condition monitoring systems by identifying gear faults at early stages. Copyright © 2015 SAE International.

Abstract

'Organization signature is a new variant of digital signature in organization transactions. It allows the employee in the organization to generate the message signature through his affiliation rather than his personal description. Certificateless public key cryptography solved the key escrow problem in identity-based cryptography, and the certificate distribution in the traditional public key infrastructure. In this paper, we present a provable secure pairing-free certificateless organizational signature scheme. Our scheme is more computationally efficient because it does not depend on pairings. The new scheme is provably secure in the random oracle model, assuming the hardness of elliptic curves discrete logarithm problem.' © 2015 John Wiley & Sons, Ltd.

Abstract

Installation of a Photovoltaic (PV) system needs an accurate design and evaluation test for the performance of its modules before using them in a system. This can be fulfilled with high accuracy in the laboratory without using commercial PV modules by using a PV emulator the PV emulator introduces a suitable tool which easily permits emulating PV system component with different parameters, teaching its characteristic and training researchers in this field the main purpose of this paper is introducing the development of a Photovoltaics (PV) emulator has the capability of emulate commercial PV modules with different parameters and under different environmental condition (irradiance or temperature change), constructing a PV array based on the series and parallel numbers of modules the PV emulator was implemented using a real-time algorithm representing the PV array mathematical model and generating the reference output power from a programmable DC power supply the PV model is simulated in MATLAB and interfaced to the real world through dSPACE using an evolutionary graphic user interface (GUI). This laboratory PV emulator is tested with real-time execution of PV model for the steady state and dynamic operating conditions. © 2015 IEEE.

The effect of pomegranate fruit extract on testosterone-induced BPH in rats

(2015) Prostate, 75 (7), pp. 679-692.

DOI: 10.1002/pros.22951

^a Department of Pharmacology and Toxicology, Faculty of Pharmacy, Ain Shams University, Cairo, Egypt

^b Vancouver Prostate Centre, Department of Urologic Sciences, University of British Columbia, Vancouver, BC, Canada

^c Department of Pharmacology and Toxicology, Helwan University, Helwan, Egypt

Abstract

Background Benign prostatic hyperplasia (BPH) affects many men after the age of 50 years. Inflammation and oxidative stress along with apoptotic changes are thought to play an important role in the pathology of BPH. Pomegranate contains a variety of polyphenolic compounds that have been studied in a medley of diseases for their anti-oxidant, anti-inflammatory and pro-apoptotic properties. Therefore, this study examined the effect of Pomegranate Fruit Extract (PFE) on the development of BPH using a testosterone-induced BPH model in rats. Methods A total of 48 rats were randomly divided into six groups of eight, one group served as the control, BPH was induced by testosterone 3 mg/kg S.C. daily in four groups, three of them received PFE by oral gavage daily at doses of 25, 50, and 100 mg/kg respectively, while one group received PFE at a dose of 50 mg/kg without induction of BPH. Results PFE at a dose of 100 mg/kg was the most effective in decreasing testosterone-induced increase in prostate weight, prostate weight/body weight ratio, and PAP levels by 30.8%, 55%, and 68% respectively and in preventing the

accompanying histological changes. In the BPH model, testosterone significantly decreased GSH, SOD, and CAT to 0.45, 0.64, and 0.88 of the control group values respectively, and significantly increased MDA by >6-fold. In combination with testosterone, PFE dosed at 100 mg/kg significantly increased GSH, SOD, and CAT to 0.83, 0.92, and 0.93 of the control group values respectively, whereas MDA was significantly decreased by 72% compared with the testosterone treated group. In addition to this, at the range of doses studied, PFE lowered COX-II, iNOS, Ki-67 expression, and increased apoptotic index. CONCLUSION The current findings elucidate the effectiveness of PFE in preventing testosterone-induced BPH in rats. This could be attributed, at least partly, to its anti-oxidant, anti-inflammatory, and pro-apoptotic properties. © 2015 Wiley Periodicals, Inc.

Abstract

In the title compound, C₁₄H₁₅N₅O₅S, the tautomer present in the solid state is that in which the immediately exocyclic N atom bears the H atom. The central five-membered ring is almost planar (r.m.s. deviation = 0.025 Å), but both its N atoms are significantly pyramidalized. A classical hydrogen bond from the N - H group to the cyanide N atom forms inversion-symmetric dimers, which are further linked by C - H...O interactions.

Abstract

Overvoltage is a concerning issue among Gulf Cooperation Council (GCC) nations during the winter light load period. This paper presented a review of the recent reactive compensation studies conducted by Oman Electricity Transmission Company (OETC) for the Main Interconnected System (MIS) of the Sultanate of Oman, regarding to its new 400 kV transmission systems. Discussions about challenges and possible solutions were outlined to highlight the unique operating nature of Middle East electrical infrastructures. Simulation results were presented to demonstrate the impact of 400 kV systems on the existing MIS grid. This paper serves as a contrasting example of voltage stability issues encountered by western utilities. © 2015 IEEE.

Nowadays and based on the globalization in the markets, optimization in manufacturing enterprises is strongly recommended and addressed to identify the time and cost to be sustainable. Although there are several issues/aspects that must be incorporated to achieve the targeted sustainability index, optimizing these indexes still need more attention from academicians and practitioners. The main goal of this paper is to optimize the sustainability index taking into consideration time and cost criteria. To achieve this goal, sustainability models were developed based on two mathematical formulations: minimum sustainable time and minimum sustainable cost. These sustainability optimization models are taken into consideration the triple bottom line (TBL): economic; social and environmental aspects and their associated issues/aspects. © 2015 The Authors. Organic interactive displays: A bridge from history(2015) *Procedia Computer Science*, 52 (1), pp. 1053-1058.**DOI:** 10.1016/j.procs.2015.05.109

Helwan University, Faculty of Computers and Informatics, Cairo, Egypt

Abstract

Novel organic forms of interactive displays are developed recently from flexible materials that can bend, fold or roll between the hands of its user giving him a wholly new sense of digital interactive media. In this paper, we hold a survey for different OUIs (Organic User Interfaces) and categorize them into four main categories: flat surfaces, non-flat surfaces, digital substrates and handheld devices. Each of which has its uses that suites certain contexts and does not fit others. We discuss each category thoroughly with its possible sub-categories, examples and applications. Each category is noticed to have a physical design that has a great deal of resemblance to the physical form or design of a pharaonic monumental style or type of artifacts from the history of ancient Egypt. The paper highlights the observed resemblance between organic digital displays and ancient monumental displays with respect to the similarities and differences in the sense that they are both used as information displays for targeted users in certain contexts. This unintended physical resemblance points out to where we might inspire novel designs for digital content on interactive displays. © 2015 The Authors. Published by Elsevier B.V.

Abstract

Autophagy is originally described as the main catabolic pathway responsible for maintaining intracellular nutritional homeostasis that involves the formation of a unique vacuole, the autophagosome, and the interaction with the endosome-lysosome pathways. This conserved machinery plays a key role in immune-protection against different invaders, including pathogenic bacteria, intracellular parasites, and some viruses like herpes simplex and hepatitis C virus. Importantly, autophagy is linked to a number of human diseases and disorders including neurodegenerative disease, Crohn's disease, type II diabetes, tumorigenesis, cardiomyopathy, and fatty liver disease. On the other hand, inflammasomes are multiprotein platforms stimulated upon several environmental conditions and microbial infection. Once assembled, the inflammasomes mediate the maturation of pro-inflammatory cytokines and promote phagosome-lysosome fusion to sustain an innate immune response. The intersections between autophagy and inflammasome have been observed in various diseases and microbial infections. This review highlights the molecular aspects involved in autophagy and inflammasome interactions during different medical conditions and microbial infections. © 2015 John Wiley & Sons A/S.

Effect of spokes structures on characteristics performance of non-pneumatic tires

(2015) *International Journal of Automotive and Mechanical Engineering*, 11 (1), pp. 2212-2223.

DOI: 10.15282/ijame.11.2015.4.0185

Automotive and Tractor Engineering Department, Helwan University, Egypt

Abstract

In this paper, three different configurations of the Michelin's Tweel™, Resilient Technologies, and Bridgestone non-pneumatic tires (NPTs) are investigated by seeking compliant spoke structures. The quasi-static, two-dimensional analysis focuses on how the contact pressure, vertical tire stiffness and stresses are affected by the spoke structures and shear layer. Two cases of NPTs are investigated: (i) a tire with a composite ring and (ii) a tire without a composite ring. The results of the models were validated by comparison with four computational finite element models. The results showed that the shape of the spokes has a great effect on the tire's behavior in the second case, while the shear layer in the first case reduces the impact of the change of spokes shape especially in contact pressure distribution. © 2015 Universiti Malaysia Pahang.

Abstract

Purpose: The purpose of this paper is to design and analyze four proximal interphalangeal joint (PIP) prosthesis thorough finite element analysis (FEA) and fabricate them using rapid prototyping (RP) technique. Arthritis of the finger joints is an important pathology of the hand. Major complaints in arthritis are stiffness, deformity and severe pain. The pain is due to the inflammatory process that occurs due to pathology, which involves joint degeneration, synovial swelling and ligament and muscle stiffness. Among the surgical treatment of arthritis is Arthroplasty which involves replacing the diseased joint with an artificial joint. **Design/methodology/approach:** In this paper, four proximal interphalangeal joint (PIP) prostheses are designed, analyzed using FEA and fabricated using rapid prototyping technique. Four different prostheses "BM", "IMP", "IMP2" and "FINS" are designed using CATIA software and tested by normal daily functions such as grasp, key pinch and tip pinch tests using FEA to analyze the results based on their stress and deformation. Finally, the prostheses are fabricated using electron beam melting technology. **Findings:** This paper examined and analyzed the relative motion of PIP designs using FEA by applying varying loads to check the stability and range of motion of the PIP implant. The ANSYS summary results were analyzed depending on the minimal results of equivalent stress and deformation from the taken tests that have happened on the designed prosthesis. The results conclude that, in the grasp test, the minimal equivalent stress and deformation have happened on the "BM" and "IMP2" implants. Furthermore, in the key pinch test, minimal equivalent stress and deformation occurred on the "FINS" implant, and finally, in the tip pinch, minimal equivalent stress occurred on the "FINS" and minimal deformation has happened on the "IMP2" implant. **Research limitations/implications:** These results conclude that both "IMP2" and "FINS" share the minimum results in the taken tests, and this shows that these implants may be further studied brainstormed upon to aid innovation of a better implant design that shares both of these implants' features and shape. Nevertheless, testing in an in vivo or in vitro model to prove more of the effectiveness of these implants should be taken into consideration, and to test how the prostheses will function in an actual environment, a simulated hand can be designed and made to discover the true forces and mechanics of the fingers and the hands with the prosthesis that is implanted, as well as to know if the hand works properly. **Originality/value:** This paper examined and analyzed the relative motion of PIP designs using FEA by applying varying loads to check the stability and range of motion of the PIP implant. © Emerald Group Publishing Limited [ISSN 1355-2546].

Abstract

The present study assesses the impact of waste water discharge on the plant communities and size structure of the common woody species in Wadi El-Shees, Al-Jabal Al-Akhdar, Libya. Thirty stands were selected along two adjacent tributaries (polluted and un-polluted) in Wadi El-Shees. Sixty-five species belonging to 60 genera and 34 families were recorded, predominated with therophytes and mono-regional taxa and only one endemic species (*Arbutus pavarii*). The application of TWINSPAN on the data set, led to the recognition of 4 vegetation groups, two represented each of the polluted and un-polluted regions. Soils of the polluted area have significant higher values of organic matter, salinity, chloride and iron. Ten common woody perennials were selected for estimating the variation in their size structure in the polluted and un-polluted tributaries. These species include one shrublet, two shrubs and 7 trees.

It was found that the density and volume of all species except *A. pavarii* and *Sarcopoterium spinosum* were higher in the polluted than the un-polluted area. Four size distributions were recognized: inverse J-shaped, bell-shaped, positive and negative skewed distributions. It was concluded that pollution had significant impact on the plant density and sizes structure of the common woody plants in Wadi El-Shees. Such study may help in managing and conserving plant diversity in Northern Libya. © 2014 WILEY-VCH Verlag GmbH & Co. KGaA, Weinheim.

Abstract

This work is aimed at developing and investigating silane based organic-inorganic hybrid polyacrylamide nanocomposite possessing unique properties, which can be used to improve the corrosion inhibition of steel subjected to corrosion. The nanocomposite was prepared using dispersion radical polymerization technique. Silica/polyacrylamide nanocomposite with various concentrations have been tested as potential inhibitor against corrosion of steel in 1 M HCl solution using electrochemical techniques. The nanocomposite behave as mixed type inhibitor and forms an inhibitive layer on the metal surface. The inhibition efficiency increased with increase in concentration of silica/polyacrylamide nanocomposite. It was found that the silica/polyacrylamide nanocomposite inhibited the acid induced corrosion of steel better than experienced by silica alone. © 2015 The Authors.

Abstract

The present study aimed to investigate the efficacy of *Rosmarinus officinalis* total methanolic extract on colon cancer induced in rats. Rats were classified into 5 groups. Group (1) was control. Groups from (2) to (5) were intrarectally injected with N-methylNitrosourea (MNU) for induction of colon cancer then group (2) was left untreated (cancer group); group (3) was treated intraperitoneally with 5-fluorouracil while, groups (4 and 5) were treated orally with 1400 and 2800 mg/kg b.wt. of *R. officinalis* extract respectively. Cancer group declared significant increase in the expression levels of β-catenin and c-Myc genes in colon tissue. Furthermore, colon cancer induced-rats demonstrated significant increase in colon COX-2, cyclin D1 and survivin expression in colon tissue associated with significant elevation in the circulating levels of all studied biochemical markers. Additionally, histopathological investigation of colon tissue sections in cancer group showed dysplasia and anaplasia in the lining epithelial cells of the glandular structure. In the contrary, treatment of cancer group with 5-fluorouracil or *R. officinalis* extract showed significant decrease in the expression levels of β-catenin and c-Myc genes. Also, all treated groups exhibited marked decrease in COX-2, cyclin D1 and survivin expression in colon tissue accompanied with a significant reduction in the circulating levels of the all studied biomarkers. As well as, marked improvement in the histological structure of colon tissue was detected. In conclusion, the present study indicated that *R. officinalis* extract possess promising therapeutic role against colon cancer through their antiinflammatory property, antiproliferative capacity and apoptotic potential.

Abstract

Plant-based natural products are promising sources for identifying novel agents with potential anti-Eimeria activity. This study explores possible effects of berberine on *Eimeria papillata* infections in the jejunum of male Swiss albino mice. Berberine chloride, when daily administered to mice during infection, impairs intracellular development and multiplication of *E. papillata*, evidenced as 60 % reduction of maximal fecal output of oocysts on day 5 p.i. Concomitantly, berberine attenuates the inflammatory response, evidenced as decreased messenger RNA (mRNA) expression of IL-1 β , IL-6, TNF α , IFN γ , and iNOS, as well as the oxidative stress response, evidenced as impaired increase in malondialdehyde, nitrate, and H 2 O 2 and as prevented decrease in glutathione and catalase activity. Berberine also alters gene expression in the infected jejunum. On day 5 p.i., mRNA expression of 29 genes with annotated functions is more than 10-fold upregulated and that of 14 genes downregulated. Berberine downregulates the genes Xaf1, Itgb3bp, and Faim3 involved in apoptotic processes and upregulates genes involved in innate immune responses, as e.g., Colec11, Saa2, Klra8, Clec1b, and Crtam, especially the genes Cpa3, Fcer1a, and Mcpt1, Mcpt2, and Mcpt4 involved in mast cell activity. Additionally, 18 noncoding lincRNA species are differentially expressed more than 10-fold under berberine. Our data suggest that berberine induces hosts to exert anti-Eimeria activity by attenuating the inflammatory and oxidative stress response, by impairing apoptotic processes, and by activating local innate immune responses and epigenetic mechanisms in the host jejunum. Berberine has the potential as an anti-Eimeria food additive in animal farming. © 2015, Springer-Verlag Berlin Heidelberg.

Abstract

In the present work, ultra-high-molecular-weight polyethylene (UHMWPE) films were irradiated with 130 keV He ions. The fluence of the ion beam was ranged from 1×10^{12} to 1×10^{16} cm $^{-2}$. The chemical, morphological, and crystallite structure changes resulted from the ion bombardment were obtained using different spectroscopic techniques. These techniques were Fourier transform infrared spectrometer, scanning electron microscope, X-ray diffraction, and UV-vis spectrophotometry. The surface free energy for untreated and ion-beam-treated samples was determined by means of contact angle measurements of three different liquids. Our results showed a decrease in the crystallinity of UHMWPE and formation of C=O groups on the polymer surface for modified samples as well. A remarkable shifting in the UV-vis spectra toward lower energy and increase in the optical absorption were observed as the ion fluence increases. Measurements of the contact angle indicate remarkable increase in the surface free energy as a function of ion fluence. © 2015 Taylor & Francis.

Abstract

In this study, we have attempted to explain the influence of secondary filler on the dispersion of carbon nanotube (CNT) reinforced high density polyethylene (HDPE) nanocomposites (CNT/HDPE). In order to understand the mixed-fillers system, Montmorillonite (MMT) in addition with Maleic anhydride grafted high density polyethylene (PE-g-MA) was added to CNT/HDPE nanocomposites. It was followed by investigating their effect on the thermo-mechanical, rheological and morphological properties of the aforesaid nanocomposite. Incorporation of 3 wt% each of MMT and PE-g-MA into CNT/HDPE nanocomposites resulted to the increased values for the tensile and flexural strength (32 % increase in both), as compared to the pure HDPE matrix. The thermal analysis result showed improved thermal stability of the formulated nanocomposites. The initial decomposition temperature (T_i) for such nanocomposite with 9 wt% of MMT and 3 wt% of PE-g-MA reached to 296 °C from 265 °C (T_i for neat HDPE matrix). Addition of MMT to CNT/HDPE nanocomposites also increased the rheological properties indicating a dominating elastic response. A significant increase in loss, storage modulus and complex viscosity was observed upon addition of PE-g-MA, whereas $\tan \delta$ was found to be reduced. This might be due to better interfacial adhesion between MMT and HDPE phases that attributes to the elastic dominance. Improvement in dispersion of CNT upon addition of MMT and PE-g-MA was further supported by the morphological analysis. Transmission electron microscopy (TEM) images revealed that larger aggregates of CNTs were disappeared upon addition of these two components leading to the enhancement of thermo-mechanical properties for such composites. © 2015, The Korean Fiber Society and Springer Science+Business Media Dordrecht.

Denitrification of coke plant wastewater using a bench-scale electrodialysis unit via statistical design

(2015) *International Journal of Electrochemical Science*, 10 (2), pp. 1478-1493.

^a Chemistry Department, College of Science, Taif University, Taif, Saudi Arabia

Abstract

Nitrate content in surface and underground water increased in some areas of the world caused by runoff from some industrial processes such as coking industry. Several degradation and separation techniques have been developed to eliminate nitrate efficiently from water. Electrodialysis (ED) represents a modern progressive electromembrane technology gaining an increasing attention in wastewater recovery. In this work, a bench-scale ED unit has been used to separate nitrate from synthetic solution and industrial wastewater collected from an Egyptian coke plant. Statistical design was applied to study the influence of different parameters (time, nitrate concentration and applied potential) those affecting the nitrate removal efficiency, and a mathematical model was generated. The results on synthetic solutions showed that all studied parameters are effective. The results have been collected at a 3-D cube that showed that at high levels of parameters (25 min, 15 V and 700 ppm) the nitrate removal efficiency was almost 100%, while a small nitrate removal efficiency of about 51% was obtained at the low levels (5 min, 5 V and 100 ppm). The wastewater sample was found to contain several inorganic and organic pollutants those could be separated together with nitrate. Only 2.5 hrs is sufficient to separate about 80% of nitrate at 15 V where longer time has no pronounce

effect on nitrate separation. This is corresponding to about 15 ppm nitrate content in the output water, which is far less than the acceptable concentration of ≤ 44 ppm. After 5 hrs of ED operation, the removal efficiency of nitrate, sulphate, chloride, cyanide, ammonia phosphorus and phenol were 82, 99, 96, 99, 98, 60 and 40%, respectively. These results revealed that electrodialysis can efficiently separate nitrate and most pollutants from coking wastewater for possible re-use. Spherical particles (5-20 μm) of mainly ammonium nitrate were obtained by evaporating the rejected water after ED operation. © 2015 The Authors.

Abstract

Many studies have demonstrated that osteopontin (OPN) contributes functionally to aggressive behaviour in many tumours including breast cancer. This study aims to investigate its role as a simple biochemical marker easily measured in plasma of breast cancer patients to give an early signal for metastases and to detect its relationship to clinicopathological findings and survival. We measured plasma OPN, CA15.3 and serum alkaline phosphatase (ALP) activity in 55 patients, 28 with early stage breast cancer and 27 with bone metastasis out of whom 20 had metastasis in other sites. The median age at diagnosis for non-metastatic cases was 60 years (range 35-85) and for metastatic cases was 45.5 years (range 32-59). In the non-metastatic group, 78.57% of the patients were histologically graded as grades I and II and 21.43% as grade III tumours. In the metastatic group, 81.48% of the patients had grades I and II and 18.52% had grade III tumours; 54% of patients in the non-metastatic group were at stage II and 46% were at stage III at presentation. All patients of group II had bone metastasis, 33% had liver metastases, 25.9% had lung metastasis and 14.8% had lymph node metastasis. Patients with non-metastatic disease had a median OPN level of 55 ng/ml (range 54-150 ng/l), while those in the metastatic group had a median of 148.0 ng/l (range 56.0-156.0 ng/l), a difference which was statistically significant ($P = 0.001$). There was no statistically significant difference in the median levels of CA15.3 and ALP between both groups. The median OPN level was significantly higher with serum ALP level above 90, progesterone receptor (PR) status, bone and visceral metastasis. Median OPN was not affected significantly by menopausal status (P -value 0.3), tumour grade (P -value 0.3), estrogen receptor (ER) status (P -value 0.7), pathological type (P -value 0.42) or serum CA15.3 level (P -value 0.6). At the end of 12-year follow-up, 83% of the patients survived (92.3% in the non-metastatic versus 74.1% in the metastatic group). The estimated median survival for the whole study population at 12 years was 13 years (95% CI 8.144-17.856). The estimated median survival was 13 years (95% CI 0) and 12 years (95% CI 4.893-19.11) in patients with median OPN levels of <142 and ≥ 142 , respectively, a difference which was not statistically significant ($P = 0.343$). No statistically significant difference in overall survival OS was noticed in relation to menopausal status ($P = 0.7$), pathological type ($P = 0.4$) and hormone receptor status ($P = 0.3$). At 6-year follow-up, it was found that OS was affected by the presence of visceral metastasis, tumour grade, serum plasma level of ALP and the serum level of CA15.3 ($P = 0.0006, 0.007, 0.001$ and 0.03, respectively). However, the presence of bone metastasis did not affect OS ($P = 0.6$). Osteopontin level can be a simple biochemical marker easily measured in plasma of breast cancer patients to give early signals for metastases, but not a prognostic factor for survival. © De Gruyter Open.

Restless leg syndrome in a sample of Egyptian patients with multiple sclerosis

(2015) *Egyptian Journal of Neurology, Psychiatry and Neurosurgery*, 52 (1), pp. 55-61.

^a Department of Neurology, Ain Shams University, Egypt

^b Department of Neurology, Helwan University, Egypt

Abstract

Background: Restless leg syndrome (RLS) has been described to be common in multiple sclerosis (MS). However, the relationship between RLS and sleep quality, fatigue and clinical disability in MS patients has not been fully investigated. **Objective:** To study the frequency of RLS in a sample of Egyptian patients with MS and if it correlates with magnetic resonance imaging (MRI) findings. **Methods:** We studied fifty patients with MS compared to thirty healthy volunteers who matched patients group for age and sex as a control group. The patient group was subjected to full clinical and neurological assessment, including the diagnosis of RLS, neurological impairment was evaluated by multiple sclerosis severity scale (MSS), fatigue Descriptive Scale (FDS) for assessment of fatigue, quality of sleep by the Pittsburgh Sleep Quality Index (PSQI), Epworth sleepiness scale (ESS), and MRI of the brain and spinal cord were done. **Results:** Our results showed that RLS frequency among our sample was 20%, which is higher than control group (6.66%), and revealed that there is affection of sleep quality among RLS positive patients in comparison to RLS negative patients in which their PSQI and ESS are higher among RLS positive group. Regarding MRI lesion, there was no statistically significant difference between MS patients with RLS and those without. **Conclusion:** RLS is significantly associated with MS and can lead to sleep disturbance in MS patients. In clinical practice, the routine screening of patients for insomnia and symptoms of RLS is encouraged. © 2015, Egyptian Society of Neurology, Psychiatry, and Neurosurgery. All rights reserved.

Lipid-Lowering and hepatoprotective effects of vitis vinifera dried seeds on Paracetamol-Induced hepatotoxicity in rats

(2015) Nutrition Research and Practice, 9 (1), pp. 37-42.

DOI: 10.4162/nrp.2015.9.1.37

^a Department of Community Health Sciences, College of Applied Medical Sciences, King Saud University, Saudi Arabia

Abstract

BACKGROUND/OBJECTIVES: Red grape seeds as functional food are a good source of important bioactive components such as phenolics and antioxidants, which decrease oxidative stress that contributes to the pathogenesis of hepatotoxicity. The current study was conducted in order to evaluate the protective effect of red grape dried seeds (RGDS) on antioxidant properties lipid metabolism, and liver and kidney functions of rats with paracetamol (750 mg/kg) induced hepatotoxicity. **MATERIALS/METHODS:** RGDS was added to the basal diet at 5, 10, and 20%. Thirty five adult male rats were assigned to five groups ($n = 7$) for a six-week feeding period; group (1) normal control, group (2) induced control, groups (3, 4, and 5) fed a diet with RGPS at different levels, 5, 10, and 20%, respectively. At the end of the feeding period, animals' blood and tissues were collected for estimation of serum lipid profile, serum liver, and kidney biomarkers. The protection was measured by detecting lipid peroxidation (LPO), glutathione (GSH), superoxide dismutase (SOD), Catalase (CAT) (in liver tissues), and liver histological examination. **RESULTS:** The results showed a significant ($P < 0.05$) decrease in levels of serum cholesterol, triglycerides, low density lipoprotein (LDL-C), and very low density lipoprotein (VLDL-C), with a significant increase in level of high density lipoprotein

(HDL-C) for RGDS groups compared to induced control. Rats administered a diet containing RGDS levels produced significant ($P < 0.05$) hepatoprotection by decreasing the activities of liver enzymes, kidney parameters, and lipid peroxidation, while levels of GSH, SOD, and CAT were increased significantly to near the normal levels.

CONCLUSION: The RGDS 20% group was more effective than others against hepatotoxicity of paracetamol, which may be attributed to RGDS total phenols and antioxidant contents, which were 1.438 mg and 1.231 mg, respectively.

Abstract

Background/aim: Virulent *Pseudomonas aeruginosa* is frequently life-threatening and often challenging to treat, and the emergence of multidrug-resistant isolates presents a critical problem for patients. The aim of the study was concerned with molecular analysis of the virulence factors and antimicrobial resistance profile of multidrug-resistant *P. aeruginosa* (MDRPA). **Materials and methods:** Out of 44 MDRPA isolates, 12 isolates representing different resistance profiles and sources of samples were selected for further molecular studies. Polymerase chain reaction (PCR) approaches were applied to identify the genes implicated in antimicrobial resistance or virulence factors in the selected MDRPA isolates. **Results:** Multidrug-resistance (*pstS*), β -lactamase (IMP7, IMP10, IMP13, and IMP25), and extended spectrum β -lactamase (*blaOXA50*) genes were detected in all of the selected MDRPA isolates. However, only 4 (33%) MDRPA isolates were positive for the presence of the extended spectrum β -lactamase (*blaOXA2*) gene. Furthermore, the hemolytic phospholipase C precursor gene (*plcH*) was detected in all PCR products of the tested MDRPA isolates while the exotoxin A (*toxA*) gene was absent. Other virulence genes were detected with variable percentage in tested isolates. **Conclusion:** The statistical analysis revealed a significantly positive correlation ($r = 0.779$, $P = 0.002$) between virulence factors and antimicrobial resistance marker profiles of the tested MDRPA isolates. © TÜBİTAK.

Abstract

Caffeine, pentoxyfylline, and kallikrein are substances that affect the efficiency of sperms in the fertilization process; however, they have not been adequately studied. The present study aimed to examine the influence of caffeine, kallikrein, and pentoxyfylline on sperm motility in bovine as well as investigate their optimum concentrations for increasing the movement of sperms in bovine. Frozen bovine sperms were thawed in universal IVF medium supplemented with 1, 5, and 10 mM caffeine or pentoxyfylline or 1, 4, and 8 U/mL kallikrein and were then incubated for 30 min. Treated semen parameters were analyzed using a computer assisted semen analyzer (CASA). Data

analysis showed that the mean values concerning progression and motility of sperm increased in caffeine and pentoxyfylline treatments when compared with the kallikrein group. The obtained results revealed that kallikrein is not necessary for the improvement of bovine sperm motility. Additionally, our results revealed that 5 mM from caffeine was the best concentration added to the medium, followed by 1 or 5 mM from pentoxyfylline. Therefore, it is concluded from the present study that caffeine has hyperactivation efficacy at 5 mM concentration compared to other treatments. © 2015 Ibrahim A. H. Barakat et al.

Abstract

This paper proposes a novel four-quadrant vector controlled induction motor (IM) adjustable speed drive (ASD) system based on a recently proposed matrix converter topology called quasi-Z-source direct matrix converter (QZSDMC). The QZSDMC is formed by cascading the quasi-Z-source impedance network and the conventional direct matrix converter (DMC). The QZSDMC can provide buck-boost operation with voltage transfer ratio controlled by controlling the shoot-through duty ratio and bidirectional operation capability. The control strategy, which is based on the indirect field oriented control algorithm, is able to control the motor speed from zero to the rated value under full load condition during motoring and regenerating operation modes. The operating principle of the proposed system is presented in detail. The simulation and the real-time implementation results, using dSPACE 1103 ControlDesk, validate the high performance of the proposed four-quadrants IM-ASD based on QZSDMC system. The proposed four-quadrant vector controlled IM-ASD system based on the QZSDMC topology overcomes the voltage gain limitation of the traditional DMC and achieves buck and boost condition in four-quadrant modes with reduced number of switches, therefore achieving low cost, high efficiency, and reliability, compared with back-to-back converter. © 2014 IEEE.

Brain computer interfacing: Applications and challenges

(2015) *Egyptian Informatics Journal*, 16 (2), pp. 213-230.

DOI: 10.1016/j.eij.2015.06.002

HCI-LAB, Department of Computer Science, Faculty of Computers and Information, Helwan University, Cairo, Egypt

Abstract

Brain computer interface technology represents a highly growing field of research with application systems. Its contributions in medical fields range from prevention to neuronal rehabilitation for serious injuries. Mind reading and remote communication have their unique fingerprint in numerous fields such as educational, self-regulation, production, marketing, security as well as games and entertainment. It creates a mutual understanding between users and the surrounding systems. This paper shows the application areas that could benefit from brain waves in facilitating or achieving their goals. We also discuss major usability and technical challenges that face brain signals utilization in various components of BCI system. Different solutions that aim to limit and decrease their effects have also been reviewed. © 2015 Production and hosting by Elsevier B.V.

Document Type: Review**Source:** ScopusAhmed, A.H.^{a b}, Habtoor, A.^a**Heterogeneously depleted Precambrian lithosphere deduced from mantle peridotites and associated chromitite deposits of Al'Ays ophiolite, Northwestern Arabian Shield, Saudi Arabia**(2015) *Ore Geology Reviews*, 67, pp. 279-296.**DOI:** 10.1016/j.oregeorev.2014.12.018^a Faculty of Earth Sciences, King Abdulaziz University, Jeddah, Saudi Arabia^b Geology Department, Faculty of Science, Helwan University, Cairo, Egypt**Abstract**

The mantle section of Al'Ays ophiolite consists of heterogeneously depleted harzburgites, dunites and large-sized chromitite pods. Two chromitite-bearing sites (Site1 and Site2), about 10km apart horizontally from one another, were examined for their upper mantle rocks. Cr-spinels from the two sites have different chemistry; Cr-rich in Site1 and Al-rich in Site2. The average Cr-ratio=(Cr/(Cr+Al) atomic ratio) of Cr-spinels in harzburgites, dunites and chromitites is remarkably high 0.78, 0.77 and 0.87, respectively, in Site1, compared with those of Site2 which have intermediate ratio averages 0.5, 0.56 and 0.6, respectively. The platinum-group elements (PGE) in chromitites also show contrasting patterns from Site1 to Site2; having elevated IPGE (Os, Ir, Ru) and strongly depleted in PPGE (Rh, Pt, Pd) with steep negative slopes in the former, and gentle negative slopes in the latter. The oxygen fugacity ($\delta\log fO_2$) values deduced from harzburgites and dunites of Site1 show a wide variation under reducing conditions, mostly below the FMQ buffer. The Site2 harzburgites and dunites, on the other hand are mostly above the FMQ buffer. Two magmatic stages are suggested for the lithospheric evolution of Al'Ays ophiolite in response to a switch of tectonic setting. The first stage produced a peridotites-chromitites suite with Al-rich Cr-spinels, possibly beneath a mid-ocean ridge setting, or most likely in back-arc rift of a supra-subduction zone setting. The second stage involved higher degrees of partial melting, produced a peridotites-chromitites suite with Cr-rich Cr-spinels, possibly in a fore-arc setting. The coexistence of compositionally different mantle suites with different melting histories in a restricted area of an ophiolite complex may be attributable to a mechanically juxtaposed by mantle convection during recycling. The mantle harzburgites and dunites are apt to be compositionally modified during recycling process; being highly depleted (Site1 case) than their original composition (Site2 case). © 2014 Elsevier B.V.

(2015) *Immunological Investigations*, 44 (3), pp. 237-252.**DOI:** 10.3109/08820139.2014.988720^a Department of Microbiology and Immunology, Faculty of Pharmacy, Helwan University, Ein Helwan, Helwan, Egypt^b Department of Pharmacognosy, Faculty of Pharmacy, Helwan University, Ein Helwan, Helwan, South Cairo, Egypt^c Department of Microbiology and Immunology, Faculty of Pharmacy, Tanta University, Tanta, Gharbia, Egypt**Abstract**

A group of 11 medicinal plants, including *Lavandula pubescens*, *Trigonella foenum-graecum*, *Salsola schweinfurthii*, *Calligonum comosum*, *Silene succulenta*, *Silene villosa*, *Bogonvillea glabra*, *Cakile maritime*, *Gomphrena celosioides*, *Mirabilis jalaba*, and *Silene nocturna* growing in Egypt, were extracted and examined for their immunomodulatory and antioxidant activities. RAW 264.7 cells were recruited to investigate the immunomodulatory effect through multiple parameters analysis. First, the proliferation index of macrophages cells was evaluated revealing that *Trigonella foenum-graecum*, *Silene succulenta* and *Silene villosa* have a significant cytotoxic effect on RAW cells. Interestingly, we observed enhancement of macrophages phagocytic function of by all extracts except *Cakile maritime*, *Gomphrena celosioides* and *Silene nocturna*. Afterwards, macrophages were challenged by incubation with LPS and the effect of various extracts on inflammatory responses was investigated; the generation of NO from activated macrophage was substantially suppressed by 7 extracts namely, *Trigonella foenum-graecum*, *Calligonum comosum*, *Silene succulenta*, *Bougainvillea glabra*, *Mirabilis jalaba*, *Gomphrena celosioides* and *Silene nocturna*. TNF- α was decreased by percentage range from 3.8 to 85.8% and *Trigonella foenum-graecum* extract showed the highest inhibition of TNF- α release. All extracts except *Trigonella foenum-graecum*, *Salsola schweinfurthii*, *Silene succulenta* and *Mirabilis jalaba* significantly inhibited COX-2 production from stimulated macrophage. Moreover, evaluating the potential antioxidant activity of these extracts showed that *Trigonella foenum-graecum*, *Salsola schweinfurthii*, *Calligonum comosum*, *Bogonvillea glabra* and *Mirabilis jalaba* exhibited some antioxidant activities. Taken together, our results suggest that

some of these extracts may have a considerable antinflammatory and antioxidant effects and may be a potential therapeutic choice in the treatment of inflammatory diseases. © 2015 Informa Healthcare USA, Inc.

Abstract

The effect of sugar types, age of culture, and concentrations of 2,4-D and sucrose on somatic embryogenesis was investigated in *Cymbopogon schoenanthus* subsp. *proximus*. Six different sugar types: sucrose, fructose, maltose, glucose, galactose and lactose at 3% concentration were used for each of three 2,4-D concentration treatments (1.0, 2.0, 4.0 mg/l). ANOVA showed a significant difference at the 1% level for culture age, sugar types and interactions between 2,4-D and sugar types when mean embryo numbers of individual sugars across the four culture ages are compared. Maltose gave highest mean value, followed by sucrose and the lowest mean number was recorded with galactose. Cultures induced by galactose although low in embryo induction gave the highest mean number of shoots across the different media and culture age. Effect of different concentrations of sucrose and BA on production of number of immature somatic embryos, mature germinating somatic embryos and shoots was examined by culturing 2.5 month-old seed-derived callus onto MS medium containing 4 different sucrose concentrations (1.0, 2.0, 3.0, 4.0%) in combination with different BA concentrations (0.0, 0.025, 0.05, 0.1 mg/l). ANOVA showed significant differences at 1% level for culture age, and interactions between culture age and sucrose concentrations. Mean number of shoots on 1% sucrose for 7 months old culture was 9.4 significantly higher than number produced on all of sucrose concentrations. The efficient regeneration system will be useful for the future production of high yielding genotypes and for the conservation of the species germplasm. © 2015 Cold Spring Harbor Laboratory Press. Abstract

Abstract The present study aims at evaluating the impact of nutrients and heavy metals capture by weeds on the nutrient absorption and productivity of rice irrigated with different water sources. Plants were sampled from five farms; three irrigated with water from canals, receiving wastes discharge, and two with groundwater. The production of rice was higher in farms irrigated from canals than ground water, while the biomass of *Echinochloa crus-galli* and *Convolvulus arvensis* had a reverse trend. Moreover, *Cyperus deformis* produced large biomass, in contrast with *Eclipta alba*, in farms irrigated with canals water. Rice accumulated the lowest amounts of N, P, K, Ca and Mg as well as lower concentrations of heavy metals. *C. arvensis* accumulated the highest concentrations of N, P and Sr and lower concentrations of the remaining heavy metals, while *C. deformis* accumulated moderate nutrients, but higher heavy metals concentrations. Rice had bioaccumulation factors (BAF) less than unity for all heavy metals except Pb. However, *C. deformis* had higher BFA for most heavy metals with the highest values of Pb and Zn. *C. arvensis* had the highest of Sr and *E. crus-galli* had the highest of Cd. The CCA indicated that most soil variables have a least effect on *Oryza sativa*, *E. crus-galli* and *E. alba*. In conclusion, weeds can cause harm to rice with the following order: *C. arvensis* > *E. crus-galli* > *E. alba* > *C. deformis*. © 2015 Elsevier Ltd. All rights reserved.

Linear and Nonlinear stabilizing control of Quadrotor UAV

(2015) ICET 2014 - 2nd International Conference on Engineering and Technology, art. no. 7016810, .

DOI: 10.1109/ICEngTechnol.2014.7016810

Mechanical Power Dept., Faculty of Engineering-mataria, Helwan University, Cairo, Egypt

Abstract

Quadrotor Unmanned Arial Vehicles (UAVs) are commonly used for complex tasks such as, surveillance, search and rescue in hazard locations for its small size, lightness and robustness. However, the stability of UAVs represents a big challenge due to its high Nonlinear, multivariable, strongly coupled nature. The present work investigates two commonly-used control strategies namely, PD-control with low pass filter and Nonlinear feedback linearization control. The parameters of each controller are optimized to set the time-domain performance within specific constrains. The performances of the two control strategies are simulated and the results are validated on real experiments. The results indicate that Nonlinear control can substantially expand the region of controllable flight angles compared to linear control. It can stabilize the quadrotor system in case of multi angle disturbances. PD-controller with low passes filter shows poor performance when it synchronously controls more than one angle at the same time. © 2014 IEEE.

Abstract

Smart grids are one of the most essential infrastructure components in the world today. Power systems have been becoming more and more complex, as a result of a considerable variety of new components being added, such as High Voltage Direct Current (HVDC) and power electronic devices, and numerous recent technologies continually being put into application, such as distributed generation. In recent years, wide-area voltage and frequency measurements are used to identify different events that occur in power systems. One of the most important events is the generator trip identification. This event could be easily identified as a sudden drop in both the system voltage level and frequency. On the other hand, high-speed, reliable and scalable data communication infrastructure is crucial in both construction and operation of wide-area voltage and frequency measurements. Universal Mobile Telecommunication System (UMTS), the 3G standard for mobile communication networks, was developed to provide high speed data transmission with reliable service performance for mobile users. Therefore, UMTS is considered a promising solution for providing a communication infrastructure for WAMS. 3G based EWAMS (Egyptian Wide Area Monitoring System) is designed and implemented in Egypt through deployment a number of Frequency Disturbance Recorders (FDRs) devices on a live 220 kV/500 kV Egyptian grid to identify the location of tripped generator in the power system. WAMS systems are used for both off-line studies and real-time applications. An important feature of these systems is their ability to provide continuous dynamic measurements that are precisely time synchronized across the power system. With real-time WAMS, the continuous measurements feed out as a data stream which can be applied to on-line applications such as monitoring and control. This paper focuses on developing an efficient and reliable wide area voltage and frequency measurements through UMTS mobile communication technology in addition to the analysis these measurements using Principal Component Analysis (PCA) in order to determine a specific signature and properties for each tripped generator in the power system network. © 2014 Elsevier Ltd. Abstract

Cetyltrimethylammonium bromide (CTAB)-selective electrodes of the types carbon paste (CPE) and screen-printed sensors (SPE) based on incorporation of zeolite ionophore have been constructed. The influences of paste composition, temperature, pH of the test solution, and foreign ions on the electrodes performance were investigated. The electrodes showed Nernstian behavior with linear concentration range of 4.61×10^{-7} - 1.0×10^{-2} and 1.26×10^{-7} - 1.0×10^{-2} mol L⁻¹, slope of 57.56 ± 1.25 and 58.92 ± 0.27 mV decade⁻¹ and lower limit of detection of 4.61×10^{-7} and 1.26×10^{-7} mol L⁻¹ for modified CPE and SPE sensors, respectively. The electrodes display good selectivity for CTAB with respect to a number of common foreign inorganic and organic species. The response is not affected by pH variation between 2.0 - 8.5 and 2.0 - 9.0 for modified CPE and SPE, respectively. The sensors were successfully used for determination of CTAB both in pure solution and in different spiked real water samples. The frequently used CTAB of analytical and technical grade as well as different water samples has been successfully titrated and the results obtained agreed with those obtained with standard two phase titration method. The sensitivity of the proposed method is comparable with the official method and ability of field measurements. © 2015 The Authors.

^c Physics Department, Faculty of Industrial Education, Helwan University, Cairo, Egypt

Abstract

CuO powders were doped with barium phosphate glass with a series of $x\text{CuO}-(20-x)\text{BaO}-30\text{ZnO}-10\text{Na}_2\text{O}-40\text{P}_2\text{O}_5$ in molar ratio with ($x = 2, 4, 6, 8, 10$ and 12) were prepared by conventional quenching melts technique. FTIR transmission spectra have been carried out. The most active peaks were observed in the region from 450 cm^{-1} to 1700 cm^{-1} . FT-IR spectra were analyzed to determine and differentiate the various vibrational modes by applying a deconvolution method to the FT-IR spectra. The density has been measured by the conventional Archimedes method, molar volume were calculated and found the density and molar volume are trend in the same direction by increases the CuO contents.

Abstract

The present work describes the exfoliation of clay through crosslinking with 3-(acrylamidopropyl) trimethylammonium chloride-co- acrylamide (APTAC/AM) which made the polymer end-tethered on Na-MMT. However, the way in which APTAC/AM interacts with the surface of MMT has not yet been studied. APTAC/AM widened the gap between clay layers and facilitates comonomers penetrate into clay. The exfoliated structure of extracted nanocomposite was confirmed by Fourier transform infrared (FTIR), X-ray powder diffraction XRD, thermogravimetric analyses (TGA) and transmission electron microscopy (TEM). Results of FT-IR, TGA and XRD analyses showed that APTAC/AM interacted with clay, but to various extents. The inhibition effect of APTAC/AM-MMT on the corrosion of steel in 1.0 M HCl solution was studied by potentiodynamic polarization curves and electrochemical impedance spectroscopy (EIS) methods. All electrochemical measurements indicate that APTAC/AM-MMT functioned as a good inhibitor in 1M hydrochloric solution and inhibition efficiency increased with APTAC/AM-MMT concentration. Polarization curves indicate that APTAC/AM-MMT acts as mixed-type inhibitor. EIS spectra exhibit one capacitive loop. The charge transfer resistance (R_{ct}) increases with APTAC/AM-MMT concentration, while double layer capacitance (C_{dl}) decreases. © 2015 The Authors.

Potential role of curcumin and garlic acid against diazinon and propoxur hepatotoxicity(2015) *International Journal of Pharmaceutical Sciences Review and Research*, 33 (2), art. no. 10, pp. 50-57.

^a Chemistry department, Damietta University, Egypt

^b Chemistry department, Helwan University, Egypt

Abstract

Diazinon, an organophosphorus insecticide and propoxur, a carbamate insecticide have been used in agriculture and public health for several years. The aim of the present study was to evaluate the oxidative stress caused by the two insecticides and biochemical changes in adult male Wistar rats and to evaluate the protective effect of curcumin and garlic. Diazinon (10 mg/kg per day in corn oil), propoxur (10 mg/kg per day in corn oil) alone or with curcumin (100 mg/kg per day in corn oil) and/or garlic (20 mg/kg per day in distilled water) were given to rats (n=11) orally through gavage for four weeks. Biochemical parameters in serum [total protein, albumin, triglyceride (TG), cholesterol, uric acid, urea, creatinine, γ-glutamyl transpeptidase (γ-GT), glutamic pyruvic transaminase (GPT), glutamic oxaloacetic transaminase (GOT), lactate dehydrogenase (LDH), catalase (CAT) and total antioxidant capacity (TAC)], superoxide dismutase (SOD) and glutathione reduced (GSH) were determined in liver homogenate and malondialdehyde (MDA) was determined in RBCs. All ultrastructural changes were investigated at the end of 4th week. Results obtained showed that albumin, total protein, GOT, GPT, LDH, creatinine, urea, GSH and SOD were statistically high significance ($p<0.001$), γ-GT, uric acid, CAT, TAC and cholesterol were statistically significance ($p<0.01$) when diazinon or propoxur-treated groups compared to control group. On the other hand, GOT, GPT, LDH, GSH and SOD were statistically high significance ($p<0.001$), albumin, total protein, γ-GT, urea, CAT and TAC were statistically significance ($p<0.01$) when curcumin and/or garlic + diazinon or propoxur-treated groups compared to diazinon or propoxur-treated groups. We conclude that curcumin and garlic decreases diazinon and propoxur oxidative toxic effects and hepatotoxicity. © 2015, Global Research Online. All rights reserved.

Abstract

Diabetes mellitus is regarded as a serious chronic disease that carries a high risk for considerable complications. In folk medicine, the edible *Grewia asiatica* fruit is used in a number of pathological conditions. This study aimed to investigate the possible curative effect of *G. asiatica* fruit ethanolic extract against streptozotocin- (STZ-) induced hyperglycemia in rats. Furthermore, mechanism of antihyperglycemic action is investigated. Hyperglycemic rats are either treated with 100 or 200 mg/kg/day *G. asiatica* fruits extract. Serum glucose, liver glycogen, malondialdehyde (MDA), reduced glutathione (GSH), superoxide dismutase (SOD), interleukin- (IL-) 1 β , and tumor necrosis factor- (TNF-) α are measured. *G. asiatica* fruits extract reduces blood glucose and pancreatic MDA levels. It increases liver glycogen and pancreatic GSH contents and SOD enzyme activity. Furthermore, *Grewia asiatica* fruits extract decreases serum IL-1 β and TNF- α . The treatment also protects against STZ-induced pathological changes in the pancreas. The results of this study indicated that *G. asiatica* fruit extract exerts antihyperglycemic activity against STZ-induced hyperglycemia. The improvement in the pancreatic β -cells and antioxidant and anti-inflammatory effects of *G. asiatica* fruit extract may explain the antihyperglycemic effect. © 2015 Hala A. H. Khattab et al.

^b Department of Mechanical Engineering at Helwan, Helwan University, P.O. Box 11792, Helwan, Cairo, Egypt

Abstract

This paper assesses the linking between the three dimensions of sustainability in the manufacturing enterprises through a proposed framework approach. The major challenge in manufacturing enterprises regarding sustainability is modelling and measuring the integrating performance metrics between sustainability dimensions. The main objectives addressed in this paper are how to model a new assessment framework for measuring integrating sustainability. The dimensions of sustainability are: economic, social and environmental. They are modelled, estimated and linked into new concepts so called "economic-social, social-environmental, and environmental-economic sustainability". The proposed framework is illustrated through a hypothetical example to investigate which integrating sustainability is more significant or influence in the sustainability regarding manufacturing enterprise. The results show that social-environmental sustainability is the highest and sustainability dimensions and their associated aspects and indicators need more attention from academic and industrialists. ^b Department of Pharmacology and Toxicology, Faculty of Pharmacy, Misr University for Science and Technology (MUST), Giza, Egypt

Abstract

Context: Ulcerative colitis is a chronic inflammatory bowel disease. Recent studies reported a pivotal role of elevated intracellular calcium in this disorder. Coenzyme Q10 (CoQ10) and amlodipine are known to maintain cellular energy, decrease intracellular calcium concentration in addition to their antioxidant and anti-inflammatory properties.

Objective: The aim of this study was to evaluate the possible protective effects of CoQ10, amlodipine and their combination on ulcerative colitis. **Materials and methods:** Colitis was induced in rats by intracolonic injection of 3% acetic acid. CoQ10 (10mg/kg), amlodipine (3mg/kg) and their combination were administered for 8 consecutive days before induction of colitis. **Results:** Our results showed that administration of CoQ10, amlodipine and their combination decreased colon tissue malondialdehyde (MDA), tumor necrosis factor- α (TNF- α), interleukin-1 β (IL-1 β), prostaglandin E2 (PGE2), myeloperoxidase (MPO) and heat shock protein (HSP70) levels induced by intracolonic injection of acetic acid and restored many of the colon structure in histological examination. On the other hand, they increased superoxide dismutase (SOD) activity, adenosine-5'-triphosphate (ATP) and interleukin-10 (IL-10) colonic contents. **Discussion and conclusion:** Administration of either CoQ10 or amlodipine was found to protect against acetic acid-induced colitis. Moreover, their combination was more effective than individual administration of either of them. The protective effect of CoQ10 and amlodipine may be in part via their antioxidant, anti-inflammatory and energy restoration properties. © 2015 Informa Healthcare USA, Inc.

Abstract

The study objectives were to refine the population pharmacokinetics (PK) model, determine microbial clearance, and assess short-term pulmonary outcomes of multiple-dose azithromycin treatment in preterm infants at risk for Ureaplasma respiratory colonization. Fifteen subjects (7 of whom were Ureaplasma positive) received intravenous azithromycin at 20 mg/kg of body weight every 24 h for 3 doses. Azithromycin concentrations were determined in plasma samples obtained up to 168 h post-first dose by using a validated liquid chromatography-tandem mass spectrometry method. Respiratory samples were obtained predose and at three time points post-last dose for Ureaplasma culture, PCR, antibiotic susceptibility testing, and cytokine concentration determinations.

Pharmacokinetic data from these 15 subjects as well as 25 additional subjects (who received either a single 10-mg/kg dose [$n = 12$] or a single 20-mg/kg dose [$n = 13$]) were analyzed by using a nonlinear mixed-effect population modeling (NONMEM) approach. Pulmonary outcomes were assessed at 36 weeks post-menstrual age and 6 months adjusted age. A 2-compartment model with all PK parameters allometrically scaled on body weight best described the azithromycin pharmacokinetics in preterm neonates. The population pharmacokinetics parameter estimates for clearance, central volume of distribution, intercompartmental clearance, and peripheral volume of distribution were 0.15 liters/h • kg^{0.75}, 1.88 liters • kg, 1.79 liters/h • kg^{0.75}, and 13 liters • kg, respectively. The estimated area under the concentration-time curve over 24 h (AUC₂₄) / MIC₉₀ value was 4 h. All posttreatment cultures were negative, and there were no drug-related adverse events. One Ureaplasma-positive infant died at 4 months of age, but no survivors were hospitalized for respiratory etiologies during the first 6 months (adjusted age). Thus, a 3-day course of 20 mg/kg/day intravenous azithromycin shows preliminary efficacy in eradicating Ureaplasma spp. from the preterm respiratory tract. Estimation of Eulerian strain from tagged MRI using Optical flow(2015) *Proceedings of the 7th Cairo International Biomedical Engineering Conference, CIBEC 2014*, art. no. 7020916, pp. 63-66.**DOI:** 10.1109/CIBEC.2014.7020916

Biomedical Engineering Department, Helwan University, Cairo, Egypt

Abstract

Cardiac magnetic resonance imaging (MRI) is considered as noninvasive imaging modalities provide information on myocardial function, viability, and morphology. One of the most common MRI techniques is tagging MRI, based on this technique the deformation of the myocardium can be evaluated and some of cardiac functions can be examined. The strain of cardiac muscle one of the parameters estimated based on the estimated deformation, this estimated strain help in the examination of myocardium viability. This paper presents a mathematical model that simulates the real cardiac motion during myocardial tagging. Using this model and real data, we estimate the circumferential strain using strain tensor with Band-pass Optical flow (BPOF) technique and compare it with the estimated strain of Harmonic Phase (HARP as a golden standard technique. The results exhibit that the stain can be estimated using BPOF method with the same level of accuracy compared to HARP method, however, BPPOF provides more reliable results than HARP, with no tracking errors, at the myocardial boundaries. © 2014 IEEE.

Abstract

The pressure drop is an essential performance index to evaluate and design gas cyclone. In order to accurately predict the complex non-linear relationships between pressure drop and geometrical dimensions, a multi-fidelity surrogate, Co-Kriging is developed and employed to model the pressure drop for cyclone separators using CFD simulations dataset and Muschelknautz model. Only the inlet section dimensions, the vortex finder diameter and the cone height are significant. The Co-Kriging model is more accurate than the ordinary Kriging model. This accuracy can be further enhanced if the optimal Latin hypercube replaced the random sampling plan. In this study, five approaches are proposed and tested for sampling update for the Co-Kriging which was not covered in the literature. These approaches succeeded to enhance the model accuracy by adding few points from both the low-fidelity and high-fidelity simulations. The Co-Kriging model has been used to get a new optimized cyclone for minimum pressure drop using the genetic algorithms optimization technique. A CFD comparison between the new design and the standard Stairmand design has been performed. CFD results show that the new cyclone design is very close to the Stairmand high efficiency design in the geometrical parameter ratio (except the cone height), and superior for low pressure drop. The new cyclone design results in 22% of the pressure drop obtained by the Stairmand design at the same volume flow rate. © 2014 Elsevier B.V.

Abstract

The reaction of androstenedione with bromine gave the 16-bromo derivative 2. The latter reacted with either cyanothioacetamide or thiourea to give the 2-cyanomethylthiazole derivative 4 and the 2-aminothiazole derivative 13. Compound 4 and 13 were used under went some condensation, coupling and heterocyclization reactions to give thiophene, pyridine and pyran derivatives. The anti-inflammatory and anti-ulcer evaluations of the newly synthesized products were evaluated and the results showed that 23f showed the maximum antiulcer activity. In addition, toxicity of the most active compounds was studied against shrimp larvae and showed that compounds 2, 23c and 23f showed non-toxicity against the tested organisms. © 2015 Elsevier Inc. Abstract

Laser induced breakdown spectroscopy (LIBS) technique has been applied to quantitative mixture fraction measurements in flames. The measured spectra of different mixtures of natural gas and air are used to obtain the calibration parameters for local elemental mass fraction measurements and hence calculate the mixture fraction. The results are compared with the mixture fraction calculations based on the ratios of the spectral lines of H/N elements, H/O elements and C/(N+O) and they show good agreement within the reaction zone of the flames. Some deviations are observed outside the reaction zone. The ability of LIBS technique as a tool for quantitative mixture fraction as well as elemental fraction measurements in reacting and non-reacting of turbulent flames is feasible. © 2014 Elsevier Ltd. Abstract

In continuation of our work concerning the relation between the anticancer and anti-vascular endothelial growth factor receptor (anti-VEGFR-2) activity of some synthesized compounds, we hereby designed and prepared three new series of furochromone and benzofuran derivatives (carbonitriles, sulfonyl hydrazides and imides). The prepared compounds were evaluated for their in vitro VEGFR-2 inhibitory activity, their cytotoxicity on fifteen human cancer cell lines and their in vivo antiprostate cancer activity. The highest anti-VEGFR-2 activity was demonstrated by 6-acetyl-4-methoxy-7-methyl-5H-furo[3,2-g]chromen-5-one (3), which exhibited the same IC₅₀ value as the reference drug sorafenib (2.00×10^{-3} μM). On the other hand, most of the synthesized compounds showed potent cytotoxicity against most of the tested cell lines, in particular, the carbonitrile series (4a,b and 5a,d) which exhibited the best activity with IC₅₀ values ranging from 3.56×10^{-13} to 4.89×10^{-7} μM. Moreover, the imide series (15-17) showed the most significant in vivo antiprostate cancer activity. An in silico GOLD molecular docking study has been done to explore the binding mode of interaction of the furochromone and benzofuran derivatives to VEGFR-2 kinase, and to reveal the correlation between IC₅₀ (μM) of the enzymatic inhibition of VEGFR-2 kinase and the GoldScore fitness for further therapeutic application. Abstract

In this paper, we present a new approach to proximity structures based on the recognition of many of the entities important in the theory of ideals. So, we give a characterization of the basic proximity using ideals. Also, we introduce the concept of g-proximities and we show that for different choice of "g" one can obtain many of the known types of generalized proximities. Also, characterizations of some types of these proximities-(g₀; h₀)-are obtained. © 2015 Drustvo Matematicara Srbije. All rights reserved.

Electrochemical behavior of zirconium in succinic acid solution

(2015) *International Journal of Electrochemical Science*, 10 (6), pp. 4888-4898.

^a Department of Chemistry, College of Science, King Saud University, Riyadh, Saudi Arabia

Abstract

The influence of succinic acid concentrations on the electrochemical behavior of ZrO₂ has been investigated using open circuit potential (OCP), electrochemical impedance spectroscopy (EIS) and galvanostatic techniques. The anodic oxidation of zirconium leads to a significant improvement in the corrosion resistance of zirconium in succinic acid solution. OCP gradually increases towards noble values in 0.01 M succinic acid, while it decreases slowly to less noble values in 0.1 M succinic acid during the initial stage of monitoring and eventually attains a steady state. The film stability dependent upon the succinic acid concentration as evident from a shift in OCP

values to less noble values with increasing concentration. The results of polarization indicates that the passive layers increase in thickness with decreasing acid concentration and become less susceptible to corrosion and thus providing more protection of the underlying zirconium metal. © 2015 The Authors.

Abstract

This paper describes the production of metallic foam precursors in 'particle' form as opposed to the typical consolidated bulk compacts. Mechanical milling was used to produce coarse composite particles of aluminum and titanium di-hydride as foaming precursors. The effect of foaming temperature on the resulting products is discussed. The porosity content in the particles was found to increase with an increase in temperature. The refined TiH₂ particle size due to mechanical milling leads to limited pore sizes in foamed particles. © 2015 Acta Materialia Inc. All rights reserved.

Abstract

The objective of this study is to reach the literature reviews for Phoenix. Genus Phoenix is composed of 17 species naturally distributed in the world. It has been used for the treatment of various infectious diseases, atherosclerosis, diabetes, hypertension and cancer. The fruits of some species are rich sources of carbohydrates, dietary fibers, certain essential vitamins and minerals. This review presents a comprehensive analysis of the phytochemistry and validated pharmacological properties of the genus phoenix.

Box, 11792, Helwan, Egypt**Abstract**

Green synthesis of NiSnO₃ nanopowder was carried out via chemie douce using nickel and tin chlorides as precursors by stirring and refluxing at 80 °C. The dried dark green bimetallic oxide nanoparticle was then used for preparing the sensing electrode in the form of a screen-printed electrode (SPE). The synthesized nanoparticles were analyzed for elemental, structural, and morphological characteristics using various analytical techniques. The Fourier transform infrared (FTIR) spectrum indicated the formation of a strong Sn-O-Ni framework, while X-ray diffraction (XRD) confirmed the formation of a bimetallic oxide nanopowder of NiSnO₃. The synthesized nanoparticles were studied for hydroquinone (HQ) sensing characteristics to develop a sensitive and reproducible electrochemical sensor from 1 to 9 mM concentrations in buffer. The developed sensor exhibited a sensitivity of 6.03 µA/mM (46.38 µA/mMcm⁻²). The charge transfer studies indicated a reversible and diffusion-controlled process. To the best of our knowledge, such a material, i.e., NiSnO₃, has not been used for HQ sensors and is being reported for the first time. © MYU K.K.

Purpose - The purpose of this paper is to synthesize some novel 2-amino-6,6-dimethyl-9-phenyl-3-(phenyldiazenyl)-6,7-dihydropyrazolo-[5,1-b]quinazolin-8(5H)-one derivatives by multi-component one-pot reaction using a microwave as a new tool for green chemistry. Design/methodology/approach - An equimolar from arylazopyrazole, 5,5-dimethyl-1,3-cyclohexanedione (dimedone) and benzaldehyde derivatives was dissolved in Dimethylformamide (DMF) to be irradiated in a microwave for 15 minutes; after completion of the reaction, as indicated by Thin layer chromatograph (TLC), the reaction mixture was poured into ice water, filtered and then crystallized with an appropriate solvent. Findings - The structure of the synthesized dyes was established and confirmed for the reaction products on the basis of their elemental analysis and spectral data (MS, IR and 1H-NMR). These prepared dyes were used to print polyester and polyamide fabrics using synthetic thickener in the printing paste for the silk screen technique. The synthesized dyes are superior in terms of yield, purity, color strength and fastness properties and will lead to valuable achievements for commercial production. Originality/value - An efficient method for synthesis of pyrazoloquinazolinone dyes was designed. The novel procedure features short reaction time, moderate yields and simple workup. The authors studied its application in printing polyester and polyamide fabrics.

Abstract

This work presents a new method to prepare poly(sodium acrylate) magnetite composite nanoparticles. Core/shell type magnetite nanocomposites were synthesized using sodium acrylate as monomer and N,N-methylenebisacrylamide (MBA) as crosslinker. Microemulsion polymerization was used for constructing core/shell structures with magnetite nanoparticles as core and poly(sodium acrylate) as shell. Fourier transform infrared spectroscopy (FTIR) was employed to characterize the nanocomposite chemical structure. Transmittance electron microscopy (TEM) was used to examine the morphology of the modified poly(sodium acrylate) magnetite composite nanoparticles. These particle will be evaluated for effective anticorrosion behavior as a hydrophobic surface on stainless steel. The composite nanoparticles has been designed by dispersing nanocomposites which act as a corrosion inhibitor. The inhibition effect of AA-Na/magnetite composites on steel corrosion in 1 M HCl solution was investigated using potentiodynamic polarization curves and electrochemical impedance spectroscopy (EIS). Polarization measurements indicated that the studied inhibitor acts as mixed type corrosion inhibitor. EIS spectra exhibit one capacitive loop. The different techniques confirmed that the inhibition efficiency reaches 99% at 50 ppm concentration. This study has led to a better understanding of active anticorrosive magnetite nanoparticles with embedded nanocomposites and the factors influencing their anticorrosion performance. © 2015 by the authors; licensee MDPI, Basel, Switzerland.

Abstract

Copper nanoparticles doped on titania carbon nanofibers (Cu NPs-doped TiO₂ CNFs) were fabricated by electrospinning of a sol-gel consisting of titanium isopropoxide (TIP), polyvinylpyrrolidone (PVP) and copper(II) acetate tetrahydrate followed by sintered at 750 °C in Ar atmosphere. The photocatalytic activities of nanofibers were examined by dehydrogenation of ammonia borane (AB) under sunlight radiation. Typically, after 120 min, the obtained hydrogen equivalent was 1.95 for Cu-doped TiO₂ CNFs. Interestingly, synthesized nanofibers were shelled by thin layer from graphite which improves the chemical resistivity. © 2015 Elsevier Ltd and Techna Group S.r.l.

Abstract

The present work has main target to study the effect of additives molecular weight and composition on the flow characteristics of wax crude oil at low temperature below pour point temperature. In this respect, maleic anhydride ester-co-vinyl acetate copolymers with varied monomers feed ratios and different alkyl ester lengths, namely, dodecyl, stearyl, and behenyl alkyl chains, were prepared. These polymeric materials were characterized by FTIR, ¹H NMR, and GPC. The performance of these additives as pour point depressants and flow improver for Egyptian waxy crude oil was evaluated through measurements of pour point and rheological parameters (viscosity and yield stress). It was observed that stearyl maleate-vinyl acetate copolymer with 1: 2 feed ratio shows the best efficiency as pour point depressant even at low concentration while octadecyl maleate-vinyl acetate copolymers with 2: 1 feed ratio are effective as flow improver. © 2015 Ayman M. Abstract

The reconstruction of mandible bone defects by the intraoperative planning of design implant results in the aesthetic and cosmetic deviation leading to increase surgical time and implant revision. The maxillofacial surgery can be improved using advanced manufacturing technique such as additive manufacturing technology with the medical modeling software to design patient specific implant which can custom fit the patient's jaw precisely and accurately. The commercial produced mandible reconstruction implants are of standard size and shape which needs manual bending before surgery, using trial and error method to custom fit the patient's jaw. Even a slight mismatch between the bone-plate interface results in the implant loosening and failure. With the integration of computer aided design (CAD), additive manufacturing, and advanced imaging systems (CT or MRI), the patient CT scan images are analyzed and processed using medical modeling software into a 3D format to produce a customized or patient specific design implant via additive manufacturing technique, such as fused deposition modeling and Electron beam melting technology. The produced customized implant fits accurately onto the patient's jaw, thus reducing the implant revision and surgery time. The customized mandible implant design and its fabrication using Additive manufacturing is an effective method in the mandible reconstruction surgery. In this study, a digital design route for patient specific mandible implant is proposed. © 2015 IEEE.

Abstract

Sustainability index (SI) is always emphasizing on the life of people to satisfy their basic needs and enjoy a better quality of living without compromising future generations. Sustainability or sustainable development is based on and used to balance between the three pillars/dimensions: economy, society and environment. The SD means making decisions that recognize the longer term impacts of actions on economy, society, and environment. In this paper, one case study will be analyzed and evaluated regarding sustainability through the three dimensions/pillars of sustainable development based on presented approach published by [1]. This approach is validated by using a real life case study. The results show how the framework is helpful for manufacturing firms to evaluate the sustainability index. © 2015 IEEE.

Studies on molecular characterizations of the outer membrane proteins, lipids profile, and exopolysaccharides of antibiotic resistant strain Pseudomonas aeruginosa

(2015) *BioMed Research International*, 2015, art. no. 651464, .

DOI: 10.1155/2015/651464

^a Food Science and Nutrition Department, College of Food and Agriculture Sciences, King Saud University, Saudi Arabia

^b Food Science and Nutrition, Faculty of Home Economics, Helwan University, Egypt

^c Department of Botany (Microbiology), Faculty of Science, Zagazig University, Zagazig, Egypt

Abstract

Susceptibility of the tested *Pseudomonas aeruginosa* strain to two different antibiotics, tetracycline (TE) and ciprofloxacin (CIP), was carried out using liquid dilution method. Minimum inhibitory concentrations of TE and CIP were 9.0 and 6.0 mg/100 mL, respectively. Some metabolic changes due to both, the mode of action of TE and CIP on *P. aeruginosa* and its resistance to high concentrations of antibiotics (sub-MIC) were detected. The total cellular protein contents decreased after antibiotic treatment, while outer membrane protein (OMP) contents were approximately constant for both treated and untreated cells. Sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE) analysis of the OMPs for untreated and TE and CIP treated cells indicated that the molecular changes were achieved as; lost in, induction and stability of some protein bands as a result of antibiotics treatment. Five bands (with mol. wt. 71.75, 54.8, 31.72, 28.63, and 20.33 KDa) were stable in both treated and untreated tested strains, while two bands (with mol. wt. 194.8 and 118.3 KDa) were induced and the lost of only one band (with mol. wt. 142.5 KDa) after antibiotics treatment. On the other hand, total lipids and phospholipids increased in antibiotic treated cells, while neutral lipids decreased. Also, there was observable stability in the number of fatty acids in untreated and treated cells (11 fatty acids). The unsaturation index was decreased to 56% and 17.6% in both TE and CIP treatments, respectively. The produced amount of EPSs in untreated cultures of *P. aeruginosa* was relatively higher than in treated cultures with sub-MICs of TE and CIP antibiotics. It was also observed that the amounts of exopolysaccharides (EPSs) increased by increasing the incubation period up to five days of incubation in case of untreated and antibiotic treated cultures. © 2015 Hany M. Abstract

A porous surface of Ti-HA composite was successfully fabricated by pulsed current activated sintering (PCAS), followed by leaching using diluted H₃PO₄. The Ti and HA powders were mixed at different contents of the HA, Ti-5, 10, 30 and 40wt% HA powders. The mixed powders were pressed in a coated graphite die using pulsed current activated sintering (PCAS) under pressure of 60MPa at temperature of 1000°C for 5min. The sintered Ti-HA specimens were immersed in the eight kinds of leaching solutions at room temperature for 24h. The leached specimen's surfaces were characterized using XRD, SEM, EDX and Rockwell hardness. The XRD patterns after sintering show that many phases were detected at the sintered specimen surfaces such as; Ti₂O, CaO, CaTiO₃, Ti_xP_y in addition to the remaining Ti and HA. Furthermore, the high concentration H₃PO₄ leaching solution is more efficient than the low concentration. Also the produced porous surfaces of Ti-HA materials containing more than 30% HA have a low relative density and hardness than the commercial Ti-6Al-4V ELI alloy. In a word, the presence of porous surface coated by HA will promote the nucleation of the biological apatite created with the human tissue and increase the bonding between them. So, the produced porous materials are considered so easy for the muscle cells to permeate after transplanted with high coherence. © 2014 The Authors.

Abstract

A new microsporidian species of the genus *Glugea* Thélohan, 1891 parasitising the marine teleost fish *Cephalopholis hemistiktos* Rüppell, collected from the Red Sea in Saudi Arabia, is described on the basis of microscopic and molecular procedures. Spherical and whitish xenoma were observed adhering to the intestinal wall. The numerous spores contained within these xenoma, were ovoid to pyriform and measured 4.3-6.0 µm (5.1 µm) in length and 1.8-2.9 µm (2.2 µm) in width. The spore's wall was composed of two thick layers, which were thinner in the area contacting the anchoring disk. The latter appeared at the spore's anterior pole, in an eccentric position to the longitudinal axis. A lamellar polaroplast surrounded the uncoiled portion of the polar filament projected to the basal region of the spore, giving rise to 26-29 turns with winding from the base to the anterior zone of the spore. The posterior vacuole, located at the spore's posterior pole, and surrounded by the polar filament coils, was irregular and composed of light material. Molecular analysis of the rRNA genes, including the ITS region, was performed using maximum parsimony, neighbour-joining and maximum likelihood methods. The ultrastructural features observed, combined with the phylogenetic data analysed, suggest this parasite to be a new species of the genus *Glugea*. This is the first species of this genus to be reported from Saudi Arabia and is herein named *Glugea nagelia* sp. n. © Institute of Parasitology, Biology Centre CAS.

Abstract

Proportional integral derivative (PID) control technique is the most common control algorithm applied in various engineering applications. Also, particle swarm optimization (PSO) is extensively applied in various optimization problems. This paper introduces an investigation into the use of a PSO algorithm to tune the PID controller for a semi-active vehicle suspension system incorporating magnetorheological (MR) damper to improve the ride comfort and vehicle stability. The proposed suspension system consists of a system controller that determine the desired damping force using a PID controller tuned using PSO, and a continuous state damper controller that estimate the command voltage that is required to track the desired damping force. The PSO technique is applied to solve the nonlinear optimization problem to find the PID controller gains by identifying the optimal problem solution through cooperation and competition among the individuals of a swarm. A mathematical model of a two degree-of-freedom MR-damped vehicle suspension system is derived and simulated using Matlab/Simulink software. The proposed PSO PID controlled suspension is compared to both the conventional PID controller and the passive suspension systems. System performance criteria are evaluated in both time and frequency domains, in order to quantify the success of the proposed suspension system. The simulated results reflect that the proposed PSO PID controller of the MR-damped vehicle suspension offers a significant improvement in ride comfort and vehicle stability. Two-Parameter Continuation and Bifurcation Strategies for Oscillatory Behavior Elimination from a Zymomonas mobilis Fermentation System

(2015) *Chemical Engineering and Technology*, 38 (8), pp. 1362-1370.

DOI: 10.1002/ceat.201400452

Abstract

Two-parameter continuation and bifurcation analysis strategies were applied to deal with the oscillatory phenomena of a Zymomonas mobilis ethanol fermentation system. A structured verified non-linear mathematical model considering the physiological limitations of microorganisms for a single continuous fermenter for ethanol production using Z.mobilis was built to identify the Hopf bifurcation (HB) points, which indicate the oscillatory behavior, using the inlet substrate concentration and the dilution rate as bifurcation parameters. The path of the HB points can be determined with different controlling operating parameters. It was found that with the addition of a small amount of cells or ethanol to the feed stream or by increasing the dilution rate, the oscillations could be eliminated and steady-state behavior was attained. Using a two-parameter continuation strategy, the Z.mobilis fermentation system could operate at steady state without oscillatory behavior. Two-parameter continuation and bifurcation analysis strategies were applied to control the oscillatory behavior of a Z.mobilis ethanol fermentation system. A mathematical model was built to identify the Hopf bifurcation points indicating the oscillatory behavior. The oscillations could be eliminated by adding small amounts of cells or ethanol to the feed stream or by increasing the dilution rate. © 2015 WILEY-VCH Verlag GmbH & Co. KGaA, Weinheim.

Abstract

Salmeterol xinafoate is a potent and a long-acting β_2 -adrenoceptor agonist. It is prescribed for the treatment of severe persistent asthma and chronic obstructive pulmonary disease. Different methods were used to prepare (R)-(-)-salmeterol such as: mixing a sample of 4-benzyloxy-3-hydroxymethyl- ω -bromoacetophenone with sodium lauryl sulfate and the mixture was added to the microbial culture of Rhodotorula rubra, treatment of p-hydroxyacetophenone with Eschenmoser's salt and carbonate exchange resin followed by a sequence of supported reagents and scavenging agents or via Rh-catalyzed asymmetric transfer hydrogenation. The enantioselective synthesis of (S)-salmeterol was achieved via asymmetric reduction of the azidoketone 4 by Pichia angusta yeast. Physical characteristics of salmeterol xinafoate were confirmed via: X-ray powder diffraction pattern, thermal analysis and UV, vibrational, nuclear magnetic resonance, and mass spectroscopical data. Initial improvement in asthma control may occur within 30 min following oral inhalation of salmeterol in fixed combination with fluticasone propionate. Clinically important improvements are maintained for up to 12 h in most patients. It is extensively metabolized in the liver by hydroxylation, thus increased plasma concentrations may occur in patients with hepatic impairment. © 2015 Elsevier Inc. All rights reserved.

Abstract

This article presents an intelligent controller system using hybrid approach of adaptive neuro-fuzzy inference system (LUTS) for control detrusor pressure and urethral pressure by correction disorders that occurs in the LUTS. Six types of LUTS disorders are used to test the adaptive network-based fuzzy inference system controller, which are an absence of bladder contraction caused by the nervous signal disorder, absence of bladder contraction caused by bladder muscle disorder, absence of urethra contraction caused by nervous signal disorder, obstructed urine flow disorder, irregular urine flow disorder, and intermittent urine flow disorder. Simulations were run in MATLAB 7, and the results of our work have demonstrated a very low transient response and a nonoscillating steady-state response with excellent stabilization. Abstract

Current research activities witness a special focus on the integration of DERs (distributed energy resources) and ESSs (energy storage systems) in MG (micro-grid) applications. In this paper, the coordination between MG and main grid for the required variable load demands is accomplished using EMS (Energy Management System). For this purpose, an advanced EMS in a typical MG working in grid connected mode is introduced. The developed EMS is able to determine the optimal operating strategies that minimize the energy costs, pollutant emissions, and hence

maximizing the output of the available renewable energy resources. The established EMS is formulated as a nonlinear optimization model with different equality and inequality constraints for proper solution based on the AIMMS (Advanced Integrated Multidimensional Modeling Software). The performance of AIMMS is compared with other commonly used algorithm such as GA (genetic algorithms) to clarify the efficient and robustness of AIMMS solver. © 2015 Elsevier Ltd.

Abstract

Viral gastroenteritis is a serious viral infection which affects a large number of individuals around the world, most of them being children. The infection may occur due to different viruses, for example, coxsackievirus, adenovirus, and rotavirus. There is no available cure for such infections, and the treatment mainly depends on hospitalization and administration of nutritional supports. A new antiviral agent against gastroenteritis viral infection will be a breakthrough in healthcare. Pyrrole and pyrrolopyrimidine derivatives are well known for their biological activity as antibacterial, antifungal, and anticancer agents. These compounds also proved to possess antiviral activity. Here, we synthesized novel pyrrole and pyrrolopyrimidine compounds and examined their antiviral activity. We synthesized several new pyrrole, pyrrolo[2,3-d]pyrimidine, and pyrrolo[3,2-e][1,2,4]triazolo[1,5-c]pyrimidine derivatives. The characterization of all synthesized compounds was based on microanalysis and spectral data. Moreover, we determined the non-toxic doses of these compounds on BGM, Hep-2, and MA-104 cells. We tested all the synthesized compounds for their antiviral activities against coxsackievirus B4, adenovirus type 7, and rotavirus Wa strain. Several compounds exhibited significant activities as antiviral agents. © 2015 Wiley-VCH Verlag GmbH & Co. KGaA.

Evaluation of optical flow tracking techniques in cardiac magnetic resonance: Numerical study

(2015) *Sensor Letters*, 13 (1), pp. 102-108.

DOI: 10.1166/sl.2015.3409

Department of Biomedical Engineering, Helwan University, Cairo, Egypt

Abstract

Left Ventricular contractility can be evaluated using tagging Magnetic Resonance Imaging (MRI) sequence. In this technique, a pattern of spatially varying magnetism is applied at the end diastole. Analyzing the deformation of tag pattern during the cardiac cycle has wide applications for cardiac deformation analysis. Noninvasive myocardial tagging in MRI has shown great potential in measuring and studying the motion of the heart. This paper presents a mathematical model that simulates the real cardiac motion during myocardial tagging. We synthesized both the Spatial Modulation of Magnetization (SPAMM) and complementary Spatial Modulation of Magnetization (CSPAMM) tag patterns with arbitrary spatial frequency. Using this model, we tested the performance and limitations of different Optical Flow (OF) motion tracking techniques and compare them with the performance of Harmonic Phase (HARP) analysis as a golden standard technique. The results exhibited that the OF tracking accuracy differs from point to another with a noticeable over estimation at the end of systole and realized that OF is performing better than HARP at the heart borders. Performance enhancement of a desiccant evaporative cooling system using direct/indirect evaporative cooler
(2015) *International Journal of Refrigeration*, 51, pp. 77-87.

DOI: 10.1016/j.ijrefrig.2014.12.009

Mechanical Power Engineering Department, Faculty of Engineering at El-Mattaria, Helwan University, P.O., Cairo, Egypt

Abstract

In this paper, three novel desiccant evaporative cooling system configurations are proposed, simulated and compared with the conventional system under a wide range of ambient air temperature (30: 40 °C) and humidity ratio (0.01: 0.02 kgv kga-1). In configuration-I, a direct/indirect evaporative cooling is inserted before the rotating heat exchanger. However, it is inserted after the rotating heat exchanger for system configuration-II. In configuration-III, an extra direct/indirect evaporative cooling is added in an opposite manner. Validation results confirm that, simulation and experimental results are in a good agreement with average errors of 2.23 and 3.87% for ambient air temperature and humidity ratio, respectively. Energetic analysis revealed that configuration-I has the highest cooling capacity while configuration-III has the highest thermal COP and air handling COP. Exergetic efficiency of config-III is higher than the conventional system with 54% as average value over the range of ambient air humidity. © 2014 Elsevier Ltd and IIR.

Abstract

Background/aim: β -Lactamase production is considered one of the most important resistance mechanisms among virulent *Pseudomonas aeruginosa* isolates. The aim of this study was to compare the production and antimicrobial resistance patterns of some virulence factors in extended spectrum β -lactamase (ES β L)-producing and nonproducing *P. aeruginosa* clinical isolates.

Materials and methods: Out of 183 different clinical specimens, 104 *Pseudomonas aeruginosa* isolates were recovered. The isolates were screened for ES β L production using the double disk diffusion test and phenotypic confirmatory disk diffusion test. All isolates were tested for susceptibility to 25 antimicrobials, as well as for expression of various virulence factors including pigment, hemolysin, gelatinase, protease, lipase, rhamnolipids, biofilm, and cell surface hydrophobicity. The results of ES β L producers and nonproducers were statistically compared.

Results: All isolates showed a high frequency of multiple resistance to at least 14 and up to 25 of the tested antimicrobials. Nevertheless, most virulence factors were produced at higher rates in ES β L-producing than in ES β L-nonproducing *Pseudomonas aeruginosa* isolates.

Conclusion: The results of this study suggest a correlation between ES β L phenotype and the production of some factors that are reported to be involved in the virulence of *P. aeruginosa*. © TÜbitak.

Abstract

We studied the association between the filament disappearances and solar flares during 1996-2010; we listed 639 associated filament disappearances with solar flares under temporal and spatial condition, those particular 639 filament disappearance were associated with 1676 solar flares during the period 1996-2010. The best angular distance between filament disappearances and associated solar flares ranged between 30° and 60°. The number of the associated events increased with increasing solar activity and decreased with quiet sun. The location of filament disappearances ranges between latitude ±50° and longitude ±70°. We found that longer filament disappearances have activity and ability of contemporary association with flares more than shorter filament disappearance, filament disappearance powers the associated flares more than non-associated flares events. The associated flares have higher solar flux, longer duration, and higher importance compared to non-associated flares with filament disappearance. In addition the associated filament disappearance with flares have two types depending on their duration, short-lived (<9 h), and long-lived (>9 h). © 2014 COSPAR.

^c Pharmaceutical Analytical Chemistry Department, Faculty of Pharmacy, October University for Modern Sciences and Arts, 6 October City, Egypt

Abstract

A novel ultra-performance liquid chromatography coupled to tandem mass spectrometry (UPLC-MS/MS) method was established for simultaneous determination of three hypoglycemic drugs namely; sitagliptin (STG), vildagliptin (VLG) and metformin (MET) in the presence of their degradation products and STG related impurities. Chromatographic separation was accomplished on a Hypersil gold 50 mm × 2.1 mm (1.9 µm) column, using acetonitrile and 0.2% formic acid aqueous solution as the mobile phase with a gradient elution. Electrospray ionization (ESI) source was operated in the positive ion mode. The selected reaction monitoring (SRM) mode on a triple quadrupole mass spectrometer was used to quantify the drugs utilizing the transitions of 408.12 → 235.24 (m/z), 304.33 → 154.32 (m/z), 130.12 → 71.32 (m/z) and 255.75 → 166.15 (m/z), for STG, VLG, MET and diphenhydramine (IS), respectively. The method has displayed a lower limit of detection of 1.50 ng mL⁻¹, 1.50 ng mL⁻¹ and 3.00 ng mL⁻¹ for STG, VLG and MET, respectively. The drugs were subjected to forced degradation where it was concluded that STG, VLG and MET were highly susceptible for alkaline stress conditions. In addition, the study of the degradation kinetics of the drugs has proved that the degradation follows a pseudo-first-order reaction. The proposed method was effectively applied for the analysis of laboratory prepared mixtures as well as combined pharmaceutical formulations. No significant difference was found regarding accuracy and precision upon statistical comparison of the obtained results with those of the reported method. Validation was conducted in compliance with the ICH guidelines proving the method to be selective, linear, precise and accurate. The simplicity and sensitivity of this method allows its use in the quality control of the cited drugs. © The Royal Society of Chemistry 2015.

A comparative theoretical study of three dozers` productivity

(2015) *Agricultural Engineering International: CIGR Journal*, 17 (1), pp. 68-77.

Automotive and Tractor Engineering Dept, Helwan University, Egypt

Abstract

Selection of earth moving equipment selected for a specific construction project is critical to the success of this type of work. As a step forward for enhancing the information related to such issue this research aims at clarifying the effect of some dozers` design parameters on their productivity. In this regard, three tracked dozers of high reputation brands are selected and some of their performance and design parameters are retrieved from manufacturers` published manuals. The major design parameters we believe are much influencing the have been chosen in the study are; the dozer weight, the dozer blade type, and blade capacity. The selected bulldozers` are having approximately same power to weight ratio. Empirical equations for calculating the productivity for each brand have also been developed by using data-fit program. Finally, it has been concluded that the blade capacity stands as the most significant parameter as the dozer productivity increases by 60% in average whenever the blade capacity increases by 25%. © 2015, Int. Comm. of Agricultural and Biosystems Engineering. All rights reserved.

Abstract

A series of N-aryl derivatives of pyrrole and its related derivatives of fused form (namely; tetrahydroindole and dihydroindenopyrroles) were prepared in fair to good yields. The newly synthesized compounds were confirmed using IR, 1H NMR, Mass spectral and elemental analysis. Tetrahydrobenzo[b] pyrroles Ia-d, 1,4-dihydroindeno[1,2-b]pyrroles IIa,b and pyrroles IIIa-c,e were evaluated for anticancer activity, coinciding with the antioxidant activity; using Di-Phenyl Picryl Hydrazyl (DPPH) tests. The cytotoxicity of the tested compounds (at a concentration of 100 and 200 µg /mL) was performed against HepG-2 and EACC cell lines. Compounds Ib, d and IIa showed promising antioxidant activity beside their anticancer activity. Docking studies were employed to justify the promising anticancer activity of Ib,d and IIa. Protein kinase (PKase)-PDB entry 1FCQ was chosen as target enzyme for this purpose using the MOLSOFT ICM 3.4-8C program. The docking results of the tested compounds went aligned with the respective anticancer assay results. © 2015 Bentham Science Publishers.

Abstract

Background: Early detection of hepatocellular carcinoma using serological markers with better sensitivity and specificity than alpha fetoprotein (AFP) is needed. **Aims:** The aim of this study was to evaluate the diagnostic value of serum sICAM-1, β -catenin, IL-8, proteasome and sTNFR-II in early detection of HCC. **Materials and Methods:** Serum levels of IL-8, sICAM-1, sTNFR-II, proteasome and β -catenin were measured by ELISA assay in 479 serum samples from 192 patients with HCC, 96 patients with liver cirrhosis (LC), 96 patients with chronic hepatitis C (CHC) and 95 healthy controls. **Results:** Serum levels of proteasome, sICAM-1, β -catenin and α FP were significantly elevated in HCC group compared to other groups (P -value <0.001), where serum level of IL-8 was significantly elevated in the LC and HCC groups compared to CHC and control groups (P -value <0.001), while no significant difference was noticed in patients with HCC and LC (P -value=0.09). Serum level of sTNFR-II was significantly elevated in patients with LC compared to HCC, CHC and control groups (P -value <0.001); also it was significantly higher in HCC compared to CHC and control groups (P -value <0.001). ROC curve analysis of the studied markers between HCC and other groups revealed that the serum level of proteasome had sensitivity of 75.9% and specificity of 73.4% at a cut-off value of 0.32 μ g/ml with AUC 0.803 sICAM-1 at cut off value of 778ng/ml, the sensitivity was 75.8% and the specificity was 71.8% with AUC 0.776. β -catenin had sensitivity and specificity of 70% and 68.6% respectively at a cut off value of 8.75ng/ml with an AUC of 0.729. sTNFR-II showed sensitivity of 86.3% and specificity of 51.8% at a cut off value of 6239.5pg/ml with an AUC of 0.722. IL-8 had sensitivity of 70.4% and specificity of 52.3% at a cut off value of 51.5pg/ml with AUC 0.631. **Conclusions:** Our data supported the role of proteasome, sICAM-1, sTNFR-II and β -catenin in early detection of HCC. Also, using this panel of serological markers in combination with α FP may offer improved diagnostic performance over α FP alone in the early detection of HCC.

Ride comfort enhancement of heavy vehicles using magnetorheological seat suspension

(2015) *International Journal of Heavy Vehicle Systems*, 22 (2), pp. 93-113.

DOI: 10.1504/IJHVS.2015.070448

Helwan University, Cairo, Egypt

Abstract

This paper investigates the application of a controlled MR damper for a semi-active seat suspension for heavy vehicles, enabling more appropriate control algorithm. The proposed control system consists of a system controller that calculates the desired damping force using a proportional integral derivative (PID) controller tuned using genetic algorithm (GA), and a continuous state damper controller that estimates the command voltage that is required to track the desired damping force. The controlled semi-active seat suspension is compared to a passive seat suspension for predetermined base displacements. These inputs are calculated separately from the vibration of the body mass of a passive quarter-vehicle suspension. System performance criteria are evaluated in both time and frequency domains, in order to verify the effectiveness of the proposed semi-active control algorithm. The generated results show that the proposed genetic PID controller of MR seat suspension offers a considerable enhancement of the ride comfort.

Abstract

In this work, the Cu-doped TiO₂ nanopowder was synthesized using hydrothermal method at 150°C. Commercial nanopowder of TiO₂ was mixed with CuO in 10 M NaOH solution and treated hydrothermally. The synthesized powder was characterized with FESEM, X-ray diffraction, UV-Vis, FTIR and Raman scattering to obtain elemental, structural and morphological information. Flower extracts of Dahlia Violet (DV), Rabbit flower (RF) and their mixed extract was used with commercial N719 dye and DSSC characteristics were studied under simulated condition. DSSCs of the synthesized powder were fabricated using conventional sandwich type technique and sealed with Surlyn® polymer film to avoid electrolyte leakage. The photocurrent-voltage characteristics were obtained using source-meter. It is interesting to note that the flower extract resulted in enhanced photoconversion efficiency over that of N719 dye. When the powder was sensitized with N719, 1.81% efficiency was achieved while mixed extract (ME) resulted in 3.88%, RF in 2.11% and DV in 1.83%. The study indicated that such extracts can be used for improved photoconversion properties. Copyright © 2015 American Scientific Publishers All rights reserved.

Abstract

High surface active amphiphilic nanogels based on N-isopropyl Acrylamide-co- 2-acylamido-2-methylpropane sulfonic Acid (NIPAm/AMPS) prepared via free aqueous polymerization at room temperature have been prepared to apply as thin film anticorrosive coatings. The morphology and the particle size distribution of the nanogels were characterized transmission and scanning electron microscopy (TEM and SEM) and dynamic light scattering DLS in aqueous solution. The effectiveness of the synthesized compounds as corrosion inhibitors for carbon steel in 1 M HCl was investigated by various electrochemical techniques such as potentiodynamic polarization and electrochemical impedance spectroscopy (EIS). Results obtained from both potentiodynamic polarisation and EIS measurements reveal that the NIPAm/AMPS nanogel is an effective inhibitor for the corrosion of steel in 1.0 M HCl solution. Polarization data show that NIPAm/AMPS nanogel behaves as a mixed type inhibitor. The inhibition efficiencies obtained from potentiodynamic polarization and EIS methods are in good agreement. The results showed enhancement in inhibition efficiencies with increasing the inhibitor concentrations. © 2015 The Authors.

Abstract

Although utilizing the exogenous mediators distinctly enhances the microbial fuel cell (MFC) performance, possibility

of microorganisms' toxicity, environmental aspect and cost are the main dilemmas facing wide applications. Therefore, successful applying of the yeast extract as a mediator in the baker's-yeast-based (*Saccharomyces cerevisiae*-based) MFCs would be of great interest as it will overcome all the aforementioned problems. The influence of the yeast extract addition was investigated based on the yeast cell adhesion on the surface of plain and gold-sputtered carbon paper anodes. In the case of plain carbon paper, the addition of the yeast extract considerably enhanced the performance of the yeast-based MFC, which can be attributed to the yeast extract role as growth media or as a mediator; the current and power densities increased from 94 to 190 mA/cm² and from 12.9 to 32.6 mW/cm², respectively. However, compared with the plain carbon paper, in the case of gold-sputtered anode the performance significantly increased with yeast extract addition, whereas it drastically decreased without yeast extract; the current and power densities increased from 25 to 300 mA/cm² and from 2 to 70 mW/cm², respectively. The obtained results indicated that yeast extract can be exploited as an effective mediator in the *Saccharomyces cerevisiae*-based MFCs. © 2015 American Chemical Society.

Abstract

We have studied the relationship between filament disappearances with CMEs during solar period 1996-2010. We used the observed disappearing filaments in H_α data from Meudon given in NOAA, and coronal mass ejections data (CMEs) from SOHO/LASCO. We obtained 278 CME events (14%) contemporary filament disappearances and CME ejections (from a total of 2018 filament disappearance events and 15,874 CME events during 1996-2010). We found that the number of associated CME-filament disappearance events increased with the increase of the solar activity and significantly decreased with quiet sun. The longer filament disappearances have activity and ability to contemporary association with CMEs more than shorter filament disappearances. The filament disappearance powers the associated CMEs. CMEs which are associated with filament disappearance are ejected with higher speeds, massive, more energetic, and smaller angular width compared to non-associated CME events. In addition, the associated filament disappearance CMEs have two types depending on their duration; short-lived (<9 h), and long-lived (>9 h). © 2014 COSPAR.

Abstract

The genus *Sophora* belongs to Fabaceae family, contains about 52 species that are widely distributed in Asia. Several phytochemical, *in vivo* and *in vitro*, experiments in addition to clinical practices have demonstrated that *Sophora* has many phyto-constituents and possesses valuable pharmacological and therapeutic properties. The total polyphenolic's content, antioxidant, cytotoxic, and antidiabetic activities of *Sophora japonica* leaves were investigated

along with their bio-guided chromatographic isolated polyphenolic constituents. Tested fractions from chromatographic separation of 80 % MeOH extract of *S. japonica* leaves revealed remarkable antioxidant(s) activity accompanied with some cytotoxic and antidiabetic activities. Moreover, six known polyphenolic constituents isolated from these fractions were identified: tamarixetin, ellagic acid 4-O- α -L-arabinofuranoside, sissotrin, rutin, gallic acid, and quercetin. Abstract

The target fragmentation in 60A and 200A GeV ^{16}O interactions with emulsion nuclei is analyzed. The validity of the nuclear limiting fragmentation hypothesis is confirmed at ultrarelativistic energies. The emission mechanism of the fast target proton (grey particle) is investigated in terms of the multiplicity characteristics. The anisotropy ratio and asymmetry parameter, while found to be independent of the projectile size or incident energy, are dependent on the target size and system centrality. This dependence is insignificant for heavy targets and in more central regions, where constancy exists. In this species, the system of the grey particle emission cannot exhibit the optimum symmetry or asymmetry between the forward and backward hemispheres. It is seen that these target protons originate from two emission sources in the earlier stage of the target fragmentation. One them emits nucleons isotropically in the 4π space. The other is the main emission source, which emits nucleons, in the forward hemisphere only, as a result of the binary nucleon-nucleon collisions and (or) intranuclear cascade. © 2015 Published by NRC Research Press.

Abstract

Reducing energy consumption is a critical issue in the design of battery-powered real time systems to prolong battery life. With dynamic voltage scaling (DVS) processors, energy consumption can be reduced efficiently by making appropriate decisions on the processor speed/voltage during the scheduling of real time tasks. Scheduling decision is usually based on parameters which are assumed to be crisp. However, in many circumstances the values of these parameters are vague. The vagueness of parameters suggests that to develop a fuzzy logic approach to reduce energy consumption by determining the appropriate supply-voltage/speed of the processor provided that timing constraints are guaranteed. Intensive simulated experiments and qualitative comparisons with the most related literature have been conducted in the context of dependent real-time tasks. Experimental results have shown that the proposed fuzzy scheduler saves more energy and creates feasible schedules for real time tasks. It also considers tasks priorities which cause higher system utilization and lower deadline miss time. Copyright © 2015 Institute of Advanced Engineering and Science. All rights reserved.

Abstract

The present study was planned to investigate the role of sex hormone receptor gene expression in the pathogenesis of hepatocellular carcinoma (HCC). Adult male Wistar rats were divided into seven groups. Group (1) was negative control. Groups (2), (5), (6), and (7) were orally administered with N-nitrosodiethylamine for the induction of HCC, then group (2) was left untreated, group (5) was orally treated with curcumin, group (6) was orally treated with carvacrol, and group (7) was intraperitoneally injected with doxorubicin, whereas groups (3) and (4) were orally administered only curcumin and carvacrol, respectively. The HCC group showed significant upregulation in the androgen receptor (AR) and the estrogen receptor-alpha (ER α) gene expression levels in the liver tissue. On the contrary, HCC groups treated with either curcumin or carvacrol showed significant downregulation in AR and ER α gene expression levels in the liver tissue. In conclusion, the obtained data highlight that both AR and ER α but not estrogen receptor-beta (ER β) gene expression may contribute to the male prevalence of HCC induced in male rats. Interestingly, both curcumin and carvacrol were found to have a promising potency in alleviating the male predominating HCC.

Hydrodynamic characteristics of a butterfly valve controlling Al<inf>2</inf>O<inf>3</inf>/water nanofluid flow
(2015) *International Journal of Fluid Mechanics Research*, 42 (3), pp. 227-235.

DOI: 10.1615/InterJFluidMechRes.v42.i3.40

Department of Mechanical Engineering, Faculty of Engineering at El-Mattaria, Helwan University, Cairo, Egypt

Abstract

This paper investigates computationally the reliability of the valve loss co-efficient and torque coefficient of butterfly valves when the flow is Al<inf>2</inf>O<inf>3</inf>/water nanofluid. The model is constructed and discretized according to five opening angles of 0, 20, 30, 55, and 75°. Three different inlet velocities of 1, 2 and 3 m/s were tested. The study was carried out numerical analysis using commercial CFD code FLUENT. The results revealed that the valve loss and torque coefficients are unreliable in design of the butterfly valves. © 2015 Begell House, Inc.

Abstract

In this paper, we analyzed the variations of TEC along a latitudinal East Euro-African chain, during the storm of April 5, 2010. We observed a large asymmetry between the two hemispheres. We detected the presence of a TID in the Northern hemisphere on April 5. The propagation time of the TID from high to low latitudes and the speed of the TID was determined. On April 5, 6 and 7, we observed a decrease of the TEC and changes of the NO_x in the Northern hemisphere. This depletion is caused by the large-scale thermospheric wind disturbances due to Joule heating dissipation in the auroral zone. © 2015 COSPAR.

Abstract

Digital truncated and obstructed Hamming apertures are used in confocal laser scanning microscope (CLSM) to improve the resolution. The resultant point spread function (RPSF) and the coherent transfer function of the defined microscope, using the modified Hamming apertures, are computed. The mammographic images are used in the CLSM to test resolution of the investigated apertures. The image is computed from the modulus square of the convolution product of the RPSF and the complex amplitude of the object. A comparison with the images obtained in case of circular uniform apertures is investigated. Another application on holography allows the recognition of the modulated Hamming apertures. © 2015 Taylor & Francis.

Abstract

Mill scale is a very attractive industrial waste due to its elevated iron content (about = 69.33% Fe) besides being suiTab. for direct recycling to the blast furnace via sintering plant. In this paper the characteristics of raw materials and the briquettes produced from this mill scale were studied by different methods of analyses. The produced briquettes were reduced with different amounts of coke breeze at varying temperatures, and the reduction kinetics was determined. The activation energy of this reaction ≈ 61.5 kJ/mole for reduction of mill scale with coke breeze in the form of briquettes with 2% molasses where the chemical reaction interface model is applicable. © 2015 International Institute for the Science of Sintering (IIS). Abstract

Sensitive disposable potentiometric sensors for determination of pioglitazone hydrochloride (PIO) have been constructed. The fabricated screen printed electrodes (SPEs) are based on multi-walled carbon nanotubes - polyvinyl chloride (MWNT-PVC) composite and crown ether as sensing ionophore. Electrode matrices compositions were optimized referring the effect of nature and content the sensing ionophore, anionic sites, plasticizer and nanomaterial. Detailed investigation revealed that sensors incorporated with 15-crown-5 ether as sensing ionophore, sodium tetrakis (4-florophenyl) borate (NaTFPB) as anionic site and 2-fluorophenyl 2-nitrophenyl ether (f-PNPE) as membrane plasticizer showed the best electroanalytical performances. The fabricated electrodes worked satisfactorily in the PIO concentration range from 10⁻⁶ to 10⁻² mol L⁻¹ with Nernstian compliance of 61.05±0.5 mV decade⁻¹ and detection limit of 8×10⁻⁷ mol L⁻¹. Carbon nanotubes remarkably improved the potential stability and lifetime of the fabricated sensors. The sensors have been successfully applied for the potentiometric determination of PIO in pharmaceutical preparations under batch experiments and flow injection analysis (FIA) with acceptable average recoveries. The relative simple fabrication protocol of disposable sensor, high sensitivity and stability of the method represents a promising approach for drug quality control laboratories. © 2015 The Authors.

Mechanism of endothelial cyto-protective and thrombo-resistance effects of sildenafil, vardenafil and tadalafil in male rabbit

(2015) *Archives of Medical Science*, 11 (1), pp. 190-198. Cited 1 time.

DOI: 10.5114/aoms.2013.33616

Department of Biochemistry and Molecular Biology, Faculty of Pharmacy, Helwan University, P.O. Box 11790, Cairo, Egypt

Abstract

Introduction: PDE5 inhibitors (PDE5inh)s have proven to be of great impact in the treatment of numerous human extra-sexual diseases and their chronic use may induce endothelial rehabilitation. This study aimed to assess the effects of PDE5inh at chronic administration to explore the possible endothelial cyto-protective and thrombo-resistance effects. Material and methods: One hundred New Zealand white male rabbits were divided into four groups. The first group (control, C) received 1 ml saline/kg, the second group (S) received 10 mg/kg sildenafil, the third group (V) received 2 mg/kg vardenafil, and the fourth group (T) received 2 mg/kg tadalafil in saline I.P. three times weekly for 4 weeks. Blood samples were collected and plasma was isolated for determination of 2,3-dinor-6-keto-prostaglandin F-1α (PGF1α), 11-dehydro- TXB2 (TXB2), fibrinogen, calcium levels, prothrombin (PT), and thrombin times (TT). Results: PDE5inh significantly increase PGF1α, calcium levels, PT and TT ($p < 0.001$) when compared with baseline data or with the saline group at the end of treatment. In contrast, PDE5inh significantly decrease TXB2 and fibrinogen levels ($p < 0.001$) when compared either with their baseline data or with the saline group at the end of treatment. The tadalafil group showed a lower increase in PGF1α ($p < 0.001$), lower decrease in TXB2 ($p < 0.001$), and higher increase in calcium levels ($p < 0.01$, $p < 0.05$), lower increase in PT and TT levels ($p < 0.001$) when compared with sildenafil or vardenafil. Conclusions: The prolonged use of PDE5inh has time-dependent mild to moderate endothelial cyto-protective, thrombo-resistance anti-inflammatory and antinociception effects via activation of endothelial NOS (eNOS), increase of PGI2 synthesis and decrease of fibrinogen with significant increase in PT and TT. ^c Department of Mathematics, Faculty of Science, Ain Shams University, Cairo, Egypt

Abstract

We explore possible signatures for heavy neutrinos and a neutral gauge boson, Z' , in the TeV scale B-L extension of the Standard Model with inverse seesaw mechanisms at the Large Hadron Collider. We show that, due to new decay channels of Z' into heavy/inert neutrinos, the LHC stringent bounds imposed on the Z' mass can be significantly relaxed. We analyze the pair production of heavy neutrinos decaying to four leptons plus two neutrinos, four jets plus two leptons, or three leptons plus two jets and one neutrino. We show that the $4l+2v$ is the most promising decay channel for probing both Z' and heavy neutrinos at the LHC. © 2014 American Physical Society.

Study of the parameters affecting radon gas flux from the stream sediments at Seila area Southeastern desert, Egypt

(2015) *Environmental Earth Sciences*, 73 (12), pp. 8035-8044.

DOI: 10.1007/s12665-014-3958-2

^a Nuclear Materials Authority, Cairo, Egypt

^b Department of Physics, Faculty of Science, Helwan University, Cairo, Egypt

Abstract

Fifty-one locations distributed on two sites at Seila area, Southeastern desert of Egypt, were chosen to study the effect of the local controlling parameters, namely the activity concentration of ^{238}U , density, and porosity of the stream sediments on the radon gas flux at this area. The average value of the activity concentration of ^{238}U in the stream sediments at the first site is 41.68 Bq kg^{-1} while it is 37.34 Bq kg^{-1} at the second site. These values are higher than the worldwide average of 33 Bq kg^{-1} . The average value of the radon flux density from the stream sediments into the atmosphere is much lower than the worldwide value of $0.016 \text{ Bq m}^{-2} \text{ s}^{-1}$ at both sites of the studied area. It may be recommended for reliable radon measurements inside the stream sediments for any application that the porosity of these sediments should be studied to estimate the suitable hole depth. The passive measurements conclude that the radon concentrations are sensitive to the local parameters while the active measurements reflect the diurnal variations reliably. © 2014, Springer-Verlag Berlin Heidelberg.

Fate of ^{14}C -ethion insecticide in the presence of deltamethrin and dimilin pesticides in cotton seeds and oils, removal of ethion residues in oils, and bioavailability of its bound residues to experimental animals

(2014) *Journal of Agricultural and Food Chemistry*, 62 (51), pp. 12287-12293.

DOI: 10.1021/jf504010h

Abstract

Ethyl- ^{14}C -ethion and some of its degradation products have been prepared for comparison purposes. Cotton plants were treated with ^{14}C -ethion alone and in the presence of deltamethrin and dimilin pesticides under conditions simulating local agricultural practice. ^{14}C -Residues in seeds were determined at harvest time; about 47.5% of ^{14}C -

activity was associated with oil. After further extraction of seeds with ethanol, the ethanol-soluble ¹⁴C-residues accounted for 10.6% of the total seed residues, whereas the cake contained about 37.3% of the total residues as bound residues in the case of ethion only. The bound residues decreased in the presence of deltamethrin and dimilin pesticides and amounted to 8.1 and 10.4% of the total residues, respectively. About 95% of the ¹⁴C-activity in the crude oil could be eliminated by simulated commercial processes locally used for oil refining. Chromatographic analysis of crude cotton oil revealed the presence of ethion monooxon, O,O-diethyl phosphorothioate, and O,O-diethyl phosphoric acid in addition to one unknown compound in the case of ethion alone or ethion and dimilin. The same degradation products are found in the case of ethion and deltamethrin in addition to ethion dioxon, whereas ethanol extract revealed the presence of ethion dioxon and O,O-diethyl phosphoric acid as free metabolites. Acid hydrolysis of the conjugated metabolites in the ethanol extract yielded O,O-diethyl S-hydroxymethyl phosphorodithioate. The bound residues were quite readily bioavailable to the rats. After feeding rats with the cake containing ethion-bound residues, a substantial amount (60%) of ¹⁴C-residues was eliminated in the urine, whereas the ¹⁴C-residues excreted in expired air and feces were 10 and 9%, respectively. About 11% of the radioactive residues were distributed among various organs. © 2014 American Chemical Society.

Abstract

2,4-Dichlorophenoxy acetic acid (2,4-D) is a well-known plant auxin which is widely used in plant tissue culture experiments as well as a weed killer and a herbicide. In this study, 2,4-D was rediscovered as a new anti-inflammatory agent through an in silico molecular modeling and docking studies along with drug formulation and in vivo anti-inflammatory inspection. The molecular modeling and docking studies indicated high affinity of 2,4-D toward COX-2 enzyme in a way similar to Ibuprofen, suggesting a higher anti-inflammatory activity. Molecular docking by both MOE 2013.08 and Leadit 2.1.2 revealed excellent binding pattern compared to some of well-known non-steroidal anti-inflammatory drugs. 2,4-D was formulated in different gel bases. In vitro drug release experiments were used to examine the best 2,4-D formula for in vivo studies. In vivo carrageenan-induced hind paw edema inflammatory model in rats was used to test the in silico finding. 2,4-D showed potential in vivo anti-inflammatory activity and significantly reduced the concentration of prostaglandin E2 in hind paw tissues in a way similar to Ibuprofen. These results may open the door to introduce a new anti-inflammatory molecule; especially that 2,4-D is a well-investigated regarding its toxicity and side effect. © 2014 Elsevier B.V.

Desiccant system for water production from humid air using solar energy

(2015) *Energy*, . Article in Press.

DOI: 10.1016/j.energy.2015.06.125

Mechanical Power Engineering Dept., Faculty of Engineering at El-Mattaria, Helwan University, P.O. 11718, Cairo, Egypt

Abstract

Decentralized and remote areas suffer from fresh water shortage. A new sustainable energy technique called "Water Extraction from Atmospheric Air" is introduced as a beneficial solution for this problem. This system involves the

absorption of water vapor from ambient air during the night time. Then, simultaneous desiccant regeneration and water vapor condensation during the day time will be occurred. In this study, a trapezoidal prism solar collector with four fiberglass sidesis designed and constructed. This collector has multi-shelves bed (desiccant carrier) in order to maximize bed surface area inside the collector. Consequently, the absorption and evaporation surfaces are increased. The experimental work shows the effect of weather conditions in system operation for both day time and night time. The regeneration and absorption processes are discussed for each operation condition. Also, different host materials (cloth and sand) with calcium chloride solution are investigated. An illustrative comparison between different bed types is demonstrated. The results revealed that the total evaporated water for cloth and sand bed can reach 2.32 and 1.23slit/daysm² at initial saturation concentration (30%) of CaCl_2 . However, the system efficiency is 29.3 and 17.76% for cloth and sand bed, respectively. © 2015 Elsevier Ltd.

Abstract

Three simple, accurate, reproducible, and selective methods have been developed and subsequently validated for the simultaneous determination of Moexipril (MOX) and Hydrochlorothiazide (HCTZ) in pharmaceutical dosage form. The first method is the new extended ratio subtraction method (EXRSM) coupled to ratio subtraction method (RSM) for determination of both drugs in commercial dosage form. The second and third methods are multivariate calibration which include Principal Component Regression (PCR) and Partial Least Squares (PLSs). A detailed validation of the methods was performed following the ICH guidelines and the standard curves were found to be linear in the range of 10-60 and 2-30 for MOX and HCTZ in EXRSM method, respectively, with well accepted mean correlation coefficient for each analyte. The intra-day and inter-day precision and accuracy results were well within the acceptable limits. © 2014 Elsevier B.V. All rights reserved.

Abstract

Herein, novel hybrid compounds of celecoxib and 2-aminoanthraquinone derivatives have been synthesized using condensation reactions of celecoxib with 2-aminoanthraquinone derivatives or 2-aminoanthraquinone with celecoxib derivatives. Celecoxib was reacted with different acid chlorides, 2-chloroethylisocyanate and bis (2-chloroethyl) amine hydrochloride. These intermediates were then reacted with 2-aminoanthraquinone. Also the same different acid chlorides and 2-chloroethylisocyanate were reacted with 2-aminoanthraquinone and the resulting intermediates were reacted with celecoxib to give isomers for the previous compounds. The antitumor activities against hepatic carcinoma tumor cell line (HEPG2) have been investigated in vitro, and all these compounds showed promising activities, especially compound 3c, 7, and 12. Flexible docking studies involving AutoDock 4.2 was investigated to identify the potential binding affinities and the mode of interaction of the hybrid compounds into two protein tyrosine kinases namely, SRC (Pp60v-src) and platelet-derived growth factor receptor, PDGFR (c-Kit). The compounds in this study have a preferential affinity for the c-Kit PDGFR PTK over the non-receptor tyrosine kinase SRC (Pp60v-src). © 2014 by the authors; licensee MDPI, Basel, Switzerland.

Abstract

2-(2-Furyl)-1H-benzimidazoles 3-11 were synthesized and tested for their in vitro VEGF inhibition in MCF-7 cancer cell line. Compound 5a was more potent than Tamoxifen, and compounds 3b, 5a, 5c, 6b, 7a and 10 showed promising potency. Furthermore, compounds (6b, 7a and 10) showed remarkable selective inhibition of COX-2 enzyme close to that of Celecoxib. Additionally, docking studies were performed using AutoDock 4.2 into the VEGFR2 kinase. Significant correlation exists between the biological activity (IC_{50} and %VEGF inhibition) against MCF-7 cell line and the molecular docking results (K_i and ΔG_b) with correlation coefficients (R^2) of 0.5513 and 0.4623 respectively. Accordingly, most of the synthesized 2-(2-furyl)-1H-benzimidazoles showed strong antiangiogenic activity against VEGFR2 kinase. © 2014 Elsevier Masson SAS. All rights reserved.

In type-II superconductors at T = 0 the critical current density is determined by the pinning of flux lines. Considering an arbitrarily shaped energy landscape the pinning force at each pinning site is given by the derivative of the flux line energy with respect to the considered direction. At finite temperatures, in addition, thermal activation can lead to a depinning of flux lines. The governing property in this case is the depth of the corresponding pinning potential, i.e. the pinning energy. We show a detailed analysis of both pinning forces and pinning energies of MgB₂ films with inhomogeneous microstructure. We show that a pronounced increase of the pinning energy is responsible for the significantly enhanced stability of the dissipation-free current transport in thin inhomogeneous MgB₂ films. This is found even if the corresponding pinning forces are small. © 2014 Elsevier B.V. All rights reserved.

The rapid growth of social media on the Web, such as forum discussions, reviews, blogs, micro-blogs, social networks and Twitter has created huge volume of opinionated data in digital forms. Therefore, last decade showed growth of sentiment analysis task to be one of the most active research areas in natural language processing. In this work, the problem of classifying documents based on overall sentiment is investigated. The main goal of this work is to present comprehensive investigation of different proposed new term weighting schemes for sentiment classification. The proposed new term weighting schemes exploit the class space density based on the class distribution in the whole documents set as well as in the class documents set. The proposed approaches provide positive discrimination on frequent and infrequent terms. We have compared our new term weighting schemes with traditional and state of art term weighting schemes. Some of our proposed terms weighting schemes outperform the traditional and state of art term weighting schemes results. © 2015 Elsevier B.V.

Abstract

The novel photocatalyst of M-doped TiO₂ nanoparticles in TUD-1 siliceous mesoporous material, M-TiO₂-TUD-1 (M = Cr or V), was synthesized in one-pot highly-controlled synthesis procedure. Three samples were prepared for this study; the first prepared with Si/Ti ratio of 2.5 without any dopant. In the second and the third; 2 wt. % of titanium were replaced by chromium and by vanadium, respectively. The obtained materials were characterized by means of elemental analysis, N₂ sorption measurements, x-ray powder diffraction (XRD), UV-Vis and Raman spectroscopy, scanning electron microscopy (SEM) as well as high resolution transmission electron microscopy (HR-TEM). The characterization results showed that all samples contain nanoparticles of TiO₂ (anatase phase, average size of 4-5 nm) embedded in the mesopores of the amorphous siliceous TUD-1, with a co-existence of Cr⁶⁺ or V⁵⁺ ions. The prepared materials were used to photocatalyze the decolorization of methyl orange (MO) in aqueous medium as a model compound under the illumination of visible light ($\lambda = 420$ nm). The photocatalytic performance of TiO₂-TUD-1 mesoporous material showed higher decolorization rate than the commercial TiO₂. The performance of TiO₂-TUD-1 was highly improved by doping with Cr and V. The order of the catalytic activity of the applied photocatalysts was Cr-TiO₂-TUD-1 > V-TiO₂-TUD-1 > TiO₂-TUD-1 > TiO₂ Hombikat. The effect of the support, i.e. TUD-1 versus MCM-41 was also investigated, the performance of Cr-TiO₂-TUD-1 was two times better than Cr-TiO₂-MCM-41. © 2014 Elsevier B.V.

Abstract

In this paper, a comparative study of the effect of different converter topologies on the iron loss of nonoriented electrical steel is presented. Three converter topologies are considered in this investigation; namely: two-, three-, and five-level power converters. Moreover, the effect of the carrier frequency on both the iron loss and converter loss is introduced. The experimental results show a dramatic increase of the iron loss for the two-level converter, especially for low levels of the carrier frequency. Furthermore, the increase of the iron loss is negligible for the multilevel converter topologies. Specifically, the use of the five-level converter, even at a low value of the carrier frequency, results in lower iron losses than the three-level converter at a relatively higher carrier frequency. © 1965-2012 IEEE.

Risk based life cycle assessment conceptual framework for energy supply systems in large buildings

(2015) *Journal of Cleaner Production*, . Article in Press.

DOI: 10.1016/j.jclepro.2015.04.075

^a Department of Mechanical and Industrial Engineering, College of Engineering, Qatar University, Doha, Qatar

^b Faculty of Energy Systems and Nuclear Science, University of Ontario Institute of Technology, Ontario, Canada

^c Faculty of Industrial Education, Helwan University, Cairo, Egypt

Abstract

This paper proposes an environmental assessment framework that integrates the conventional life cycle assessment (LCA) with risk assessment for the purpose of evaluating energy conservation systems in buildings from environmental and societal perspectives. The inclusion of the potential risks raised by the different stakeholders in this framework will help the LCA professionals to identify accurate system boundaries of their study. This research addresses some limitations of frameworks presented so far by providing process activity modeling, using Type-zero method of integrated definition language, IDEF0, as a tool to describe each phase of its application. The proposed framework considers the LCA risk-based analysis in three modules namely; (i) establish of the life cycle stages, (ii) identify risk indicators and perform risk assessment, and (iii) manage risks through applying the risk assessment results to the life cycle of building's energy system. The risk based life cycle assessment (RBLCA) framework proposed here is further explained in a case study of performing RBLCA for a hybrid energy supply system (HESS) that supplies power to a hotel building. This approach allows us to investigate unfavorable impacts and risks of using HESS as way for energy conservation. © 2015 Elsevier Ltd.

Abstract

Epitaxial bilayers of the high-temperature-superconductor YBa₂Cu₃O_{7-δ} (YBCO) and the ferromagnetic metal La_{0.67}Ca_{0.33}MnO₃ (LCMO) were prepared by pulsed laser deposition on (1 1 0)-oriented SrTiO₃ substrates, such that the CuO₂ planes of YBCO are perpendicular to the YBCO-LCMO interface. X-ray diffraction and Raman scattering demonstrate complete (1 1 0) orientation of both YBCO and LCMO overlayers. The resistivity and magnetization of the bilayer films are highly anisotropic. The critical temperatures for superconductivity and ferromagnetism as well as the saturation magnetization exhibit modest reductions compared to corresponding bulk values. © 2014 Elsevier B.V. Abstract

Monodispersed silver nanoparticles capped by pectin were prepared by the reaction of silver nitrate with alkali hydrolyzed pectin at 70 °C for 30 min. Spherical and size-regulated silver nanoparticles were prepared using alkali hydrolyzed pectin as a reducing and particle-stabilizing agent. This approach is facile, effective, rapid, and convenient for the large scale preparation of silver nanoparticles. UV-visible spectral analysis confirmed that the nanoparticles consisted of metallic silver. Transmission electron microscopy (TEM) was used to estimate particle size and size distribution of the produced silver nanoparticles. Transmission electron microscopy and size distribution analysis revealed the presence of spherical silver nanoparticles with a main diameter of 5-10 nm and have a narrow size distribution. The concentration of reducing sugars was monitored by using dinitrosalicylic acid. A comprehensive schematic mechanism for the formation of silver nanoparticles using pectin is proposed. © 2014 Elsevier Ltd.

Abstract

A new method to prepare silver nanoparticles was reported. Alginate colloidal solution containing chemically synthesized silver nanoparticles (AgNPs) was investigated regarding the nanoparticles stabilization and possibilities for production of alginate based nanoparticles. The formation of AgNPs has been confirmed by UV-visible spectroscopy and monitoring of reducing sugars in the reaction was carried out. The morphology of synthesized silver nanoparticles was characterized by transmission electron microscopy (TEM). The results showed that the morphology of Ag nanoparticles is spherical and the main size is about 1-4 nm. © 2014 Elsevier Ltd.

Abstract

The CMS collaboration considers upgrading the muon forward region which is particularly affected by the high-

luminosity conditions at the LHC. The proposal involves Gas Electron Multiplier (GEM) chambers, which are able to handle the extreme particle rates expected in this region along with a high spatial resolution. This allows to combine tracking and triggering capabilities, which will improve the CMS muon High Level Trigger, the muon identification and the track reconstruction. Intense R&D has been going on since 2009 and it has lead to the development of several GEM prototypes and associated detector electronics. These GEM prototypes have been subjected to extensive tests in the laboratory and in test beams at the CERN Super Proton Synchrotron (SPS). This contribution will review the status of the CMS upgrade project with GEMs and its impact on the CMS performance. © CERN 2014.

Abstract

During 2013 and 2014 (Long Shutdown LS1) the CMS experiment is upgrading the forward region installing a fourth layer of RPC detectors in order to complete and improve the muon system performances in the view of the foreseen high luminosity run of LHC. The new two endcap disks consists of 144 double-gap RPC chambers assembled at three different production sites: CERN, Ghent (Belgium) and BARC (India). The chamber components as well as the final detectors are subjected to full series of tests established in parallel at all the production sites. All assembly and test operations have been engineered in order to standardize and improve detector production. In this work the complete chamber construction, quality control procedures and preliminary results will be detailed. © CERN 2014, published under license by IOP Publishing Ltd and Sissa Medialab srl.

Development of thrombus-resistant and cell compatible crimped polyethylene terephthalate cardiovascular grafts using surface co-immobilized heparin and collagen

(2014) *Materials Science and Engineering C*, 43, pp. 538-546. Cited 3 times.

DOI: 10.1016/j.msec.2014.07.059

Abstract

Short-term patency of polyethylene terephthalate (PET) cardiovascular grafts is determined mainly by the inherent thrombogenicity and improper endothelialization following grafts implantation. The aim of the present study was to immobilize heparin to develop thrombus resistant grafts. Additionally, collagen was co-immobilized to enhance the host cell compatibility. The synthetic woven and knitted forms of crimped PET grafts were surface modified by Denier reduction to produce functional carboxyl groups. The produced groups were used as anchor sites for covalent immobilization of heparin or co-immobilization of heparin/collagen by the end-point method. The modified surface was characterized using Fourier transform infrared spectroscopy and X-ray photoelectron spectroscopy. The biological activity of immobilized molecules was investigated in vitro using direct blood coagulation test, and "platelet deposition under flow condition. Furthermore, the biocompatibility of modified grafts with host cells was assessed using L929 cell as model. All modified grafts showed significant resistance against fibrin and clot formation. The number of deposited platelets on heparin-immobilized woven and knitted grafts obviously decreased by 3 fold and 2.8 fold per unit surface area respectively, while the heparin/collagen co-immobilized grafts showed only a decrease by 1.7 and 1.8 fold compared to unmodified PET. Heparin-immobilized grafts reported no significant effect on L929 cells adhesion and growth ($P > 0.05$), conversely, collagen co-immobilization considerably increased cell adhesion almost ~ 1.3 fold and 2 fold per unit surface area for woven and knitted grafts respectively. Our results emphasize that immobilization of heparin minimized the inherent thrombogenicity of the PET grafts. The simultaneous co-immobilization of collagen supported host cell adhesion and growth required for the grafts biocompatibility. © 2014 Elsevier B.V.

Comparative study in the use of neural networks for order of magnitude cost estimating in construction

(2015) *Journal of Information Technology in Construction*, 19, pp. 462-473.

^a Faculty of Engineering, Helwan University, Cairo, Egypt

^b Department of Building Civil and Environmental Engineering, Concordia University, Montreal, Canada

Abstract

This paper presents a study on the use of artificial neural networks (ANNs) in preliminary cost estimating. The choice and the design of the ANN model significantly affect the results obtained from the model and, hence, the accuracy of the estimated cost. The study considered Back Propagation Neural Network (BPNN), Probabilistic Neural Network (PNN) and Generalized Regression Network (GRNN) as well as regression analysis. Models were developed for order of magnitude cost estimating of low-rise structural steel buildings and short-span timber bridges. The study was conducted on actual data for 35 low-rise structural steel buildings and their respective cost was estimated using the developed regression and ANN models. These models were also applied to estimate the cost of a timber bridge extracted from the literature. The results showed that the mean absolute percentage error (MAPE) for the neural network models ranges from 16.83% to 19.35% whereas was equal to 23.72% for the regression model. Moreover, the linear regression model was more sensitive to the change of the number of the training data and that the PNN network was the most stable network among all the other estimating models as the maximum difference in MAPE percentage was only 2.46%. Whereas, the maximum difference in MAPE was 19.47%, 17.91%, and 61.45% for BPNN, GRNN and regression models respectively. © 2014 The authors.

Abstract

This study aimed to investigate the potential protective role of *Physalis peruviana* L. (family Solanaceae) against cadmium-induced hepatorenal toxicity in Wistar rats. Herein, cadmium chloride ($CdCl_2$) (6.5mg/kg bwt/day) was intraperitoneally injected for 5 days, and methanolic extract of physalis (MEPh) was pre-administered to a group of Cd-treated rats by an oral administration at a daily dose of 200mg/kg bwt for 5 days. The findings revealed that $CdCl_2$ injection induced significant decreases in kidney weight and kidney index. Cadmium intoxication increased the activities of liver enzymes and the bilirubin level, in addition to the levels of uric acid, urea and creatinine were increased in the serum. The pre-administration of MEPh alleviated hepatorenal toxicity in Cd-treated rats. *Physalis* was noted to play a good hepatorenal protective role, reducing lipid peroxidation, nitric oxide, and enhancing enzymatic activities and non-enzymatic antioxidant molecule, glutathione, in hepatic and renal tissues of Cd-treated rats. Moreover, physalis treatment was able to reverse the histopathological changes in liver and kidney tissues and also increased the expression of Bcl-2 protein in liver and kidney of rats. Overall, the results showed that MEPh can induce antioxidant and anti-apoptotic effects and also exerts beneficial effects for the treatment of Cd-induced hepatorenal toxicity. © 2014 Elsevier Ltd.

Abstract

This paper presents a study of the performance of the Galerkin method using Legendre basis functions for solving linear Fredholm integro-differential problems. Convergence and error estimation of the method were discussed. The method is then tested on several examples. Numerical results are included and comparisons with other methods are made to confirm the efficiency and accuracy of the method. © 2014 Elsevier Inc. All rights reserved.

Abstract

Background: Snake venoms are synthesized and stored in venom glands. Most venoms are complex mixtures of several proteins, peptides, enzymes, toxins and non-protein components. In the present study, we investigated the oxidative stress and apoptosis in rat liver cells provoked by *Naja hajecrude* injection (LD_{50}) after four hours. **Methods:** Wistar rats were randomly divided into two groups, the control group was intraperitoneally injected with saline solution while LD_{50} -dose envenomed group was intraperitoneally injected with venom at a dose of 0.025 µg/kg of body weight. Animals were killed four hours after the injection. Lipid peroxidation, nitric oxide and glutathione levels were measured as oxidative markers in serum and liver homogenate. In addition, liver function parameters and activities of antioxidant enzymes were determined. **Results:** *N. hajecrude* venom (0.025 µg/kg of body weight) enhanced lipid peroxidation and nitric oxide production in both serum and liver with concomitant reduction in glutathione, catalase, glutathione reductase and glutathione-S-transferase activities. Superoxide dismutase and glutathione peroxidase activities were significantly increased in liver of envenomed rats. These findings were associated with apoptosis induction in the liver. In addition, *N. hajecrude* venom caused hepatic injury as indicated by histopathological changes in the liver tissue with an elevation in total bilirubin, serum alanine aminotransferase, aspartate aminotransferase, γ-glutamyl transpeptidase, and alkaline phosphatase. **Conclusions:** Based on the present results, it can hypothesized that *N. hajecrude* venom is a potent inducer of toxin-mediated hepatotoxicity associated with apoptosis in the liver. © 2014 Al-Quraishi et al.

Abstract

Development of new antimicrobial agents is a good solution to overcome drug-resistance problems. In this context, new functionalized thiophene, acrylamide, arylhydrazone, pyrazole and pyridone derivatives bearing sulfisoxazole moiety were designed, synthesized and evaluated for their in vitro antibacterial and antifungal activities. Among the synthesized compounds, thiophene 4d and 6-thioglucosylpyridone 17 displayed significant antibacterial activities against *Escherichia coli* (MIC, 0.007 µg/mL vs gentamycin 1.95 µg/mL) and *Bacillus subtilis* (MIC, 0.007 µg/mL vs ampicillin 0.24 µg/mL), respectively. Whereas, the pyrazole 6 showed the highest antifungal activity against *Aspergillus fumigatus* (MIC, 0.03 µg/mL vs amphotericin B 0.12 µg/mL). In general, most of the synthesized compounds exhibited better antimicrobial activities than sulfisoxazole; this might be attributed to the synergistic effect of the sulfonamide and attached heterocyclic moieties as well as the increased lipophilic characters of the synthesized compounds. Molecular docking studies indicated that the synthesized compounds could occupy both p-amino benzoic acid (PABA) and pterin binding pockets of the dihydropteroate synthase (DHPS), suggesting that the target compounds could act by the inhibition of microbial DHPS enzyme. The results provide important information for the future design of more potent antimicrobial agents. © 2014 Elsevier Ltd. All rights reserved.

Histological, molecular and biochemical detection of renal injury after *Echis pyramidum* snake envenomation in rats

(2015) *Saudi Journal of Biological Sciences*, . Article in Press.

DOI: 10.1016/j.sjbs.2014.10.003

^a Department of Zoology, College of Science, King Saud University, Saudi Arabia

^b Department of Zoology and Entomology, Faculty of Science, Helwan University, Cairo, Egypt

^c Molecular Drug Evaluation Department, National Organization for Drug Control and Research (NODCAR), Giza, Egypt

Abstract

Nephrotoxicity is a common sign of snake envenomation. The present work aimed to clarify the effect of intraperitoneal injection of 1/8 LD₅₀ and 1/4 LD₅₀ doses of *Echis pyramidum* snake venom on the renal tissue of rats after 2, 4 and 6h from envenomation. Histopathological examination showed intense dose and time dependent abnormalities, including swelling glomerulus and tubular necrosis and damage as well as signs of intertubular medullary hemorrhage at early stages of envenomation. However, at late stages of envenomation by any of the doses under investigation, no intact renal corpuscles were recorded and complete lysis in renal corpuscles with ruptured Bowman's capsules was observed. Immunohistochemistry by immunohistochemical staining was used to test the protein expression of Bax in renal tissue of rats. The result showed that the expression of Bax in renal tissue sections of envenomated rats was increased according to dose and time-dependant manner. The isolation of DNA from the renal cells of envenomed rats pointed out to the occurrence of DNA fragmentation, which is another indicator for renal tissue injury especially after 6h of 1/4 LD₅₀ of *E. pyramidum* envenomation. Oxidative stress biomarkers malondialdehyde and nitrite/nitrate levels, antioxidant parameters; glutathione, total antioxidant capacity and catalase were assayed in renal tissue homogenates. The venom induced significant increase in the levels of malondialdehyde and nitrite/nitrate while the levels of glutathione, total antioxidant capacity and catalase were significantly decreased, especially after 6h of envenomation. The results revealed that the *E. pyramidum* induced dose and time-dependant significant disturbances in the physiological parameters in the kidney. We conclude that the use of the immunohistochemical techniques, the detection of DNA integrity and oxidative stress marker estimations are more specific tools that can clarify cellular injury and could point out to the defense activity of the renal tissue at envenomation. © 2014 The Authors.

Abstract

Eimeriosis, a widespread infectious disease of livestock, is caused by coccidian protozoans of the genus *Eimeria*. These obligate intracellular parasites strike the digestive tract of their hosts and give rise to enormous economic losses, particularly in poultry, ruminants including cattle, and rabbit farming. Vaccination, though a rational prophylactic measure, has not yet been as successful as initially thought. Numerous broad-spectrum anti-coccidial drugs are currently in use for treatment and prophylactic control of eimeriosis. However, increasing concerns about parasite resistance, consumer health, and environmental safety of the commercial drugs warrant efforts to search for novel agents with anti-Eimeria activity. This review summarizes current approaches to prevent and treat eimeriosis such as vaccination and commercial drugs, as well as recent attempts to use dietary antioxidants as novel anti-Eimeria agents. In particular, the trace elements selenium and zinc, the vitamins A and E, and natural products extracted from garlic, barberry, pomegranate, sweet wormwood, and other plants are discussed. Several of these novel anti-Eimeria agents exhibit a protective role against oxidative stress that occurs not only in the intestine of *Eimeria*-infected animals, but also in their non-parasitized tissues, in particular, in the first-pass organ liver. Currently,

it appears to be promising to identify safe combinations of low-cost natural products with high anti-Eimeria efficacy for a potential use as feed supplementation in animal farming. © 2014 Springer-Verlag Berlin Heidelberg.

Abstract

Surface water quality monitoring is one of the responsibilities of a number of provincial and federal environmental departments in Canada. In Saskatchewan, the Ministry of Environment is responsible for the province water quality monitoring network. The sampling effort was initiated 40 years ago and has been ongoing since, with varying degrees of spatial and temporal coverage. The main objective of the Saskatchewan monitoring network is the assessment of ambient water quality status. In addition, one of the main uses of the generated water quality data is the calculation of a Water Quality Index. The adequacy of the monitoring network to perform these tasks needs to be validated. The objective of this study is to provide a statistical assessment of two of the monitoring network main aspects, the water quality variables and their sampling frequency. A new rationalization approach is applied for the assessment and reselection of water quality variables. The proposed approach provides, in a systematic way, the optimal combinations of variables to continue measuring, variables that may be redundant and could be considered for discontinuance, and variables that may need to be added to the list of variables being measured. The confidence interval around the mean is used as the main criterion for the sampling frequency assessment. A design chart is provided for the sampling frequency assessment, which is easy to use, and provides an initial assessment of the number of samples required to provide a mean value with a predefined error percentage. © 2014 Springer International Publishing Switzerland.

Abstract

A previously reported microarray data analysis by RISS algorithm on breast cancer showed over-expression of the growth factor receptor (Grb7) and it also highlighted Tweety (TTYH1) gene to be under expressed in breast cancer for the first time. Our aim was to validate the results obtained from the microarray analysis with respect to these genes. Also, the relationship between their expression and the different prognostic indicators was addressed. RNA was extracted from the breast tissue of 30 patients with primary malignant breast cancer. Control samples from the same patients were harvested at a distance of ≥ 5 cm from the tumour. Semi-quantitative RT-PCR analysis was done on all samples. There was a significant difference between the malignant and control tissues as regards Grb7 expression. It was significantly related to the presence of lymph node metastasis, stage and histological grade of the malignant tumours. There was a significant inverse relation between expression of Grb7 and expression of both oestrogen and

progesterone receptors. Grb7 was found to be significantly related to the biological classification of breast cancer. TTYH1 was not expressed in either the malignant or the control samples. The RISS by our group algorithm developed was laboratory validated for Grb7, but not for TTYH1. The newly developed software tool needs to be improved. © 2014 Springer Science+Business Media New York.

Experimental characterization of methane inverse diffusion flame

(2014) *Combustion Science and Technology*, 186 (9), pp. 1249-1272.

DOI: 10.1080/00102202.2014.920835

Abstract

This article presents 10-kHz images of OH-PLIF simultaneously with 2-D PIV measurements in an inverse methane diffusion flame. Under a constant fuel flow rate, the central air jet Re was varied, leading to air to fuel velocity ratio, V_r , to vary from 8.3 to 66.5. Starting from $V_r = 20.7$, the flame is commonly characterized by three distinct zones. The length of the lower fuel entrainment region is inversely proportional to V_r . The flames investigated resemble a string shear layer confining this zone, and converging into the second distinct region, the flame neck zone. The third region is the rest of the flame, which spreads in a jet-like manner. The inverse diffusion flames exhibit varying degrees of partial premixing, depending upon on the velocity ratio V_r , and this region of partial premixing evolves into a well-mixed reaction zone along the flame centerline. The OH distribution correlated with the changes in the mean characteristics of the flow through reduction in the local Reynolds number due to heat release. The existence of a flame suppresses or laminarizes the turbulence at early axial locations and promotes fluctuations at the flame tip for flames with $V_r < 49.8$. In addition, the flame jet width can be correlated to the OH distribution. In upstream regions of the flames, the breaks in OH are counterbalanced by flame closures and are governed by edge flame propagation. These local extinctions were found to occur at locations where large flow structures were impinging on the flame and are associated with a locally higher strain rate or correlated to the local high strain rates at the flame hole edges without this flow impinging. Another contributor to re-ignition was found to be growing flame kernels. As the flames approach global blow-off, these kernels become the main mechanism for re-ignition further downstream of the flames. At low V_r , laminarization within the early regions of the flame provides an effective shield, preventing the jet flow from penetrating through the flame. © Copyright © 2014 Taylor & Francis Group, LLC.

Abstract

In the present paper, we have continued to study the properties of soft topological spaces. We introduce new types of soft compactness based on the soft ideal I , in a soft topological space (X, τ, E) namely, soft I -compactness, soft semi- I -compactness, soft countably- I -compactness and soft countably semi- I -compactness. Also, several of their topological properties are investigated. The behaviour of these concepts under various types of soft functions has obtained. © 2014 NSP Natural Sciences Publishing Cor.

This paper presents a three level large scale linear programming problem in which the objective functions at every level are to be maximized. A three level programming problem can be thought as a static version of the Stackelberg strategy. An algorithm for solving a three planner model and a solution method for treating this problem are suggested. At each level we attempt to optimize its problem separately as a large scale programming problem using Dantzig and Wolfe decomposition method. Therefore, we handle the optimization process through a series of sub problems that can be solved independently. Finally, a numerical example is given to clarify the main results developed in this paper. © 2014 NSP Natural Sciences Publishing Cor.

Article in Press.**DOI:** 10.1016/j.cattod.2014.07.049^a Photocatalytic Synthesis Group, Faculty of Science and Technology, MESA+ Institute of Nanotechnology, University of Twente, The Netherlands^b Chemistry Department, Faculty of Science, Helwan University, Ain Helwan, 11719 Cairo, Egypt**Abstract**

Three different synthesis techniques were applied to prepare Ti3+-containing TiO₂. The first is a self-doped technique in which TiO₂ was reduced in situ at 500 °C by NO and CO gases to produce blue powder (blue titania). The second method is a calcination treatment of a physical mixture consisting of commercial TiO₂ Hombikat and Ti₂O₃ at 600 °C to produce a yellow powder (composite). The third technique is hydrogenation of different commercially available titania (Rutile, P25, and Hombikat) samples at elevated temperatures to produce yellowish white powders. The prepared samples were characterized by means of X-ray diffraction (XRD), nitrogen physisorption measurements, diffuse reflectance UV-Vis and Raman spectroscopy, electron paramagnetic resonance (EPR) spectroscopy, and scanning electron microscopy (SEM). The photocatalytic activity of the prepared materials was tested in the decolorization reaction of methyl orange (MO) under the illumination of 'black light' ($\lambda = 375$ nm). The kinetic data of the photocatalytic reactions show that reduced titania samples exhibit higher photocatalytic activity than titania. Furthermore, the highest photocatalytic activity was obtained by hydrogenation of P25 at 500 °C. Moreover, the photo-deposition of platinum nanoparticles on the prepared materials enhanced the photocatalytic performance significantly. Titania samples which were firstly platinized and then hydrogenated were much more active than samples which were hydrogenated first and then platinized. The stability of the Ti3+ containing titania samples in aqueous conditions was found to be low, and needs to be improved to allow application in practice. © 2014 Elsevier B.V. All rights reserved.

Abstract

Background: High Density Polyethylene (HDPE) is one of the most often used polymers in biomedical applications. The limitations of HDPE are its visco-elastic behavior, low modulus and poor bioactivity. To improve HDPE properties, HA nanoparticles can be added to form polymer composite that can be used as alternatives to metals for bone substitutes and orthopaedic implant applications.
Method: In our previous work (*BioMedical Engineering OnLine* 2013), different ratios of HDPE/HA nanocomposites were prepared using melt blending in a co-rotating intermeshing twin screw extruder. The accelerated aging effects on the tensile properties and torsional viscoelastic behavior (storage modulus (G') and Loss modulus (G'')) at 80°C of irradiated and non-irradiated HDPE/HA was investigated. Also the thermal behavior of HDPE/HA were studied. In this study, the effects of gamma irradiation on the tensile viscoelastic behavior (storage modulus (E') and Loss modulus (E'')) at 25°C examined for HDPE/HA nanocomposites at different frequencies using Dynamic Mechanical Analysis (DMA). The DMA was also used to analyze creep-recovery and relaxation properties of the nanocomposites. To analyze the thermal behavior of the HDPE/HA nanocomposite, Differential Scanning Calorimetry (DSC) was used.
Results: The microscopic examination of the cryogenically fractured surface revealed a reasonable distribution of HA nanoparticles in the HDPE matrix. The DMA showed that the tensile storage and loss modulus increases with increasing the HA nanoparticles ratio and the test frequency. The creep-recovery behavior improves with increasing the HA nanoparticle content. Finally, the results indicated that the crystallinity, viscoelastic, creep recovery and relaxation behavior of HDPE nanocomposite improved due to gamma irradiation.
Conclusion: Based on the experimental results, it is found that prepared HDPE nanocomposite properties improved due to the addition of HA nanoparticles and irradiation. So, the prepared HDPE/HA nanocomposite appears to have fairly good comprehensive properties that make it a good candidate as bone substitute. © 2014 Alothman et al.; licensee BioMed Central Ltd.

Abstract

This paper presents the vertical total electron content vTEC variations for three African stations, located at mid-low and equatorial latitudes, and operating since more than 10 years. The vTEC of the middle latitude GPS station in Alexandria, Egypt (31.2167°N; 29.9667°E, geographic) is compared to the vTEC of two others GPS stations: the first one in Rabat/Morocco (33.9981°N; 353.1457°E, geographic), and the second in Libreville/Gabon (0.3539°N; 9.6721°E, geographic). Our results discussed the diurnal, seasonal, and solar cycle dependences of vTEC at the local ionospheric conditions, during different phases of solar cycle in the light of the classification of Legrand and Simon. The vTEC over Alexandria exhibits the well-known equinoctial asymmetry which changes with the phases of the solar cycle; the spring vTEC is larger than that of autumn during the maximum, decreasing and minimum phases of solar cycle 23. During the increasing phase of solar cycle 24, it is the contrary. The diurnal variation of the vTEC presents multiple maxima during the equinox from 2005 to 2008 and during the summer solstice from 2006 to 2012. A nighttime vTEC enhancement and winter anomaly are also observed. During the deep solar minimum (2006–2009) the diurnal variation of the vTEC observed over Alexandria is similar to the diurnal variation observed during quiet

magnetic period at equatorial latitudes. We observed also that the amplitude of vTEC at Libreville is larger than the amplitude of vTEC observed at Alexandria and Rabat, indeed Libreville is near the southern crest of the Equatorial Ionization anomaly. Finally, the correlation coefficient between vTEC and the sunspot number Rz is high and changes with solar cycle phases. © 2014 COSPAR.

Pomegranate extract protects against cerebral ischemia/reperfusion injury and preserves brain DNA integrity in rats

(2014) *Life Sciences*, 110 (2), pp. 61-69. Cited 2 times.

DOI: 10.1016/j.lfs.2014.06.023

Abstract

Aim Interruption to blood flow causes ischemia and infarction of brain tissues with consequent neuronal damage and brain dysfunction. Pomegranate extract is well tolerated, and safely consumed all over the world. Interestingly, pomegranate extract has shown remarkable antioxidant and anti-inflammatory effects in experimental models. Many investigators consider natural extracts as novel therapies for neurodegenerative disorders. Therefore, this study was carried out to investigate the protective effects of standardized pomegranate extract against cerebral ischemia/reperfusion-induced brain injury in rats. Main methods Adult male albino rats were randomly divided into sham-operated control group, ischemia/reperfusion (I/R) group, and two other groups that received standardized pomegranate extract at two dose levels (250, 500 mg/kg) for 15 days prior to ischemia/reperfusion (PMG250 + I/R, and PMG500 + I/R groups). After I/R or sham operation, all rats were sacrificed and brains were harvested for subsequent biochemical analysis. Key findings Results showed reduction in brain contents of MDA (malondialdehyde), and NO (nitric oxide), in addition to enhancement of SOD (superoxide dismutase), GPX (glutathione peroxidase), and GRD (glutathione reductase) activities in rats treated with pomegranate extract prior to cerebral I/R. Moreover, pomegranate extract decreased brain levels of NF-κB p65 (nuclear factor kappa B p65), TNF-α (tumor necrosis factor-alpha), caspase-3 and increased brain levels of IL-10 (interleukin-10), and cerebral ATP (adenosine triphosphate) production. Comet assay showed less brain DNA (deoxyribonucleic acid) damage in rats protected with pomegranate extract. Significance The present study showed, for the first time, that pre-administration of pomegranate extract to rats, can offer a significant dose-dependent neuroprotective activity against cerebral I/R brain injury and DNA damage via antioxidant, anti-inflammatory, anti-apoptotic and ATP-replenishing effects. © 2014 Elsevier Inc.

^c Department of Medical Oncology, National Cancer Institute, Cairo University, Cairo, Kasr el Eini, Egypt

Abstract

Background: Matrix metalloproteinases (MMPs) have long been associated with cancer-cell invasion and metastasis. Few studies are available that describe this association with bladder cancer either related or unrelated to schistosoma infection. Evaluating the urinary levels of MMP3 and MMP9 as diagnostic and prognostic biomarkers in different

stages of schistosomal and non schistosomal bladder cancer was the aim of the present study. Urine samples were collected from 70 patients with schistosomal and non schistosomal bladder cancer at early and advanced stages and also from 12 healthy volunteers as controls. Urinary levels of MMP-3 and MMP-9 was measured by ELISA technique. Sensitivity and specificity of both markers were determined. Results: Urinary levels of both MMP-3 and MMP-9 were significantly elevated in all bladder cancer patients compared with controls. MMP-3 started to elevate in early stages of schistosomal bladder cancer (0.173 ng/ml) and non-schistosomal bladder cancer patients (0.308 ng/ml) compared to control (0.016 ng/ml) and remained elevated in advanced stages (0.166, 0.235 ng/ml) of both types of bladder cancer patients. In contrast, MMP-9 showed a significant elevation in advanced stages only of both schistosomal and non schistosomal bladder cancer patients (10.33, 21.22 ng/ml) compared to control (0.409 ng/ml) and this elevation of both markers was much higher in non schistosomal bladder cancer. Both Metalloproteinases were specific for the diagnosis of the disease but MMP-3 was more sensitive and this sensitivity was evident in the early stage (84.85% for MMP3, 27.28% for MMP9). Conclusions: MMP3 may be the recommended urinary metalloproteinases as early diagnostic biomarker in the early stages of both types of bladder cancer although both MMP9 and MMP3 can be used in the diagnosis of advanced stages. Further studies are required on large number of urine samples to confirm these results. © 2014 El Sharkawi et al.; licensee BioMed Central.

Abstract

Surface modification of Poly (allyl diglycol carbonate) (PADC) is induced by 150 keV Ag ions of different fluences. The pristine as well as bombarded samples were investigated by UV-Vis spectroscopy, Fourier transform-infrared analysis (FTIR) and micro-hardness tester. The variations of wettability and surface free energy were determined by the contact angle measurements. The obtained results showed that ion beam bombardment induced increase in the absorption spectra of the UV-Vis with increase of ion fluence as well. The direct and indirect optical band gap decreased from 4.2 to 3.6 eV for pristine sample to 3.2 and 2.5 eV for those bombarded with Ag ion beam at the highest fluence, respectively. Changes in chemical properties were observed by Fourier transform infrared spectroscopy. Increase in the wettability, surface free energy and work of adhesion with increase the ion fluence were observed. Ion bombardment inducing increasing in a micro-hardness surface due to the high carbon surface concentration and cross-linking effects in the polymeric chains. The bombarded PADC surfaces may find special applications to the field of the micro-electronic devices and printing process. © 2014 Elsevier Ltd. All rights reserved.

Abstract

Sustainable development (SD) will be the driving force to Twenty-first Century as automation was to the Twentieth Century and stream was to Nineteenth Century. There are two levels of sustainability: Macro-Level (country, cities) and Micro-Level (manufacturing enterprises and its town and regional areas). In this paper, Micro-Level of sustainability will be discussed. The major challenge of manufacturing enterprises is modelling and assessing the sustainable development performance. Introducing indexes for sustainable development assessment in manufacturing enterprises is important not only to enable them to quantitatively estimate SD, but also to determine the

requirements of components for these enterprises to survive. The main objectives addressed in this paper is how to model the required components and how to introduce a new assessment framework for assessing sustainability from lowest levels, dimensions up to sustainable development level according to Micro-Level. The three pillars of sustainability (economic, social and environmental) are modelled, estimated and incorporated into a concept, the so-called general sustainable development index. Based on these concepts, the sustainable models will be analysed and presented through covering all aspects/issues of sustainability. The ultimate goal of this paper is considering the needs of manufacturing enterprise to be sustainable as well as to be globalised through introducing the concept of economic-social-environmental sustainable development and basic attitudes related to creating sustainable development value in engineering practices (economic), social (political) and environmental community. An industry-based case study is used to represent sustainability through aspects, performance metrics, indicators and pillars. © 2014 Taylor & Francis.

Abstract

Currently, there are no FDA approved medications for treatment of cocaine addiction underscoring the dire need to develop such a product. There is an accumulating body of evidence that L-tetrahydropalmatine (L-THP), a non-selective dopamine antagonist, can be used for the treatment of cocaine addiction. Indeed, the FDA recently approved its usage in a Phase I study in cocaine abusers and it was indispensable to develop a simple and sensitive method for the simultaneous determination of L-THP and cocaine in human plasma. We developed a UPLC-FLD method for quantitation of these molecules using an ACQUITY BEH C18 column (2.1. mm. ×. 50. mm, 1.7. µm) and a mobile phase that consisted of 10. mM ammonium phosphate (pH = 4.75), methanol, and acetonitrile (v:v:v, 78:16:6). Venlafaxine was used as the internal standard while hexane was used for the liquid-liquid extraction. The flow rate was 0.4. mL/min with fluorescence detection using an excitation wavelength of 230. nm and emission detection wavelength of 315. nm. This method was selective, linear and sensitive with a lower limit of quantification of 2.5. ng/mL for both cocaine and L-THP. The intra-day precision of cocaine and L-THP was <9.50% while the accuracy was <4.29%. The inter-day precision of cocaine and L-THP was <9.14%, and the accuracy was <12.49%. The recovery for cocaine and L-THP ranged from 43.95 to 50.02% and 54.65 to 58.31%, respectively. In comparison to forty reported cocaine quantitation methods this method is simple, sensitive and cost-effective and can be used for simultaneous quantitation of L-THP and cocaine. This method meets the FDA guidelines and can be used in current and future clinical studies. © 2014.

Abstract

Vascular smooth muscle α 2C-adrenoceptors (α 2C-ARs) mediate vasoconstriction of small blood vessels, especially arterioles. Studies of endogenous receptors in human arteriolar smooth muscle cells (referred to as microVSM) and transiently transfected receptors in heterologous HEK293 cells show that the α 2C-ARs are perinuclear receptors that translocate to the cell surface under cellular stress and elicit a biological response. Recent studies in microVSM unraveled a crucial role of Rap1A-Rho-ROCK-F-actin pathways in receptor translocation, and identified protein-protein interaction of α 2C-ARs with the actin binding protein filamin-2 as an essential step in the process. To better understand the molecular nature and specificity of this interaction, in this study, we constructed comparative models of human α 2C-AR and human filamin-2 proteins. Finally, we performed in silico protein-protein docking to provide a structural platform for the investigation of human α 2C-AR and filamin-2 interactions. We found that electrostatic interactions seem to play a key role in this complex formation which manifests in interactions between the C-terminal arginines of α 2C-ARs (particularly R454 and R456) and negatively charged residues from filamin-2 region between residues 1979 and 2206. Phylogenetic and sequence analysis showed that these interactions have evolved in warm-blooded animals.

Abstract

Background: Microarray technology, as well as other functional genomics experiments, allow simultaneous measurements of thousands of genes within each sample. Both the prediction accuracy and interpretability of a classifier could be enhanced by performing the classification based only on selected discriminative genes. We propose a statistical method for selecting genes based on overlapping analysis of expression data across classes. This method results in a novel measure, called proportional overlapping score (POS), of a feature's relevance to a classification task. **Results:** We apply POS, along-with four widely used gene selection methods, to several benchmark gene expression datasets. The experimental results of classification error rates computed using the Random Forest, k Nearest Neighbor and Support Vector Machine classifiers show that POS achieves a better performance. **Conclusions:** A novel gene selection method, POS, is proposed. POS analyzes the expressions overlap across classes taking into account the proportions of overlapping samples. It robustly defines a mask for each gene that allows it to minimize the effect of expression outliers. The constructed masks along-with a novel gene score are exploited to produce the selected subset of genes. © 2014 Mahmoud et al.; licensee BioMed Central Ltd.

Abstract

This study tested the multi-society generalizability of an eight-syndrome assessment model derived from factor analyses of American adults' self-ratings of 120 behavioral, emotional, and social problems. The Adult Self-Report (ASR; Achenbach and Rescorla 2003) was completed by 17,152 18–59-year-olds in 29 societies. Confirmatory factor analyses tested the fit of self-ratings in each sample to the eight-syndrome model. The primary model fit index (Root Mean Square Error of Approximation) showed good model fit for all samples, while secondary indices showed acceptable to good fit. Only 5 (0.06%) of the 8,598 estimated parameters were outside the admissible parameter space. Confidence intervals indicated that sampling fluctuations could account for the deviant parameters. Results thus supported the tested model in societies differing widely in social, political, and economic systems, languages,

ethnicities, religions, and geographical regions. Although other items, societies, and analytic methods might yield different results, the findings indicate that adults in very diverse societies were willing and able to rate themselves on the same standardized set of 120 problem items. Moreover, their self-ratings fit an eight-syndrome model previously derived from self-ratings by American adults. The support for the statistically derived syndrome model is consistent with previous findings for parent, teacher, and self-ratings of 1½–18-year-olds in many societies. The ASR and its parallel collateral-report instrument, the Adult Behavior Checklist (ABCL), may offer mental health professionals practical tools for the multi-informant assessment of clinical constructs of adult psychopathology that appear to be meaningful across diverse societies. © 2014, Springer Science+Business Media New York.

Surface modification of cotton fabrics for antibacterial application by coating with AgNPs-alginate composite
(2014) *Carbohydrate Polymers*, 108 (1), pp. 145-152. Cited 12 times.

DOI: 10.1016/j.carbpol.2014.03.005

Abstract

In recent years nano-sized particles have been focused on bacteriostasis. We investigated antimicrobial activities by applying AgNPs-alginate composite on cotton fabric, using a simple one-step rapid synthetic route by reduction of silver nitrate using alkali hydrolyzed alginate solution which acts as both reducing and capping agent. FTIR spectra, color coordinates, silver content, silver release percent and SEM images of treated fabric samples confirmed the successful physical deposition of AgNPs-alginate composite on the fabric. The treated fabrics demonstrated an excellent antibacterial activity against the tested bacteria, *Escherichia coli*, *Staphylococcus aureus* and *Pseudomonas aeruginosa*. A slight decrease in the antibacterial feature of the cotton fabrics was observed after successive washings. However, an efficient antibacterial activity still remained on the fabrics. © 2014 Elsevier Ltd.

The protective effect of Phoenix dactylifera L. seeds against CCl₄-induced hepatotoxicity in rats
(2014) *Journal of Ethnopharmacology*, 155 (1), pp. 736-743. Cited 1 time.

DOI: 10.1016/j.jep.2014.06.026

Department of Biochemistry and Molecular Biology, Faculty of Pharmacy, Helwan University, Cairo, Egypt

Abstract

Ethnopharmacological relevance In traditional Egyptian medicine, *Phoenix dactylifera* L. (date palm) seeds are listed in folk remedies for the management of diabetes, liver diseases and gastrointestinal disorders. The present study was conducted to investigate the protective effect of *Phoenix dactylifera* L. seeds aqueous suspension against the chemically-induced hepatic injury in rats. Methods Liver injury was achieved by exposing Wistar rats to CCl₄ (10% in olive oil; 0.5 mL/rat; IP) twice a week for 4 weeks. Along with CCl₄, aqueous suspensions of raw or roasted *Phoenix dactylifera* seeds (1.0 g/kg) were administered orally in a daily manner. Results Our results demonstrated that *Phoenix dactylifera* seeds significantly improved the CCl₄-induced alterations in liver function parameters (AST, ALT, ALP and albumin). Moreover, the CCl₄-induced oxidative stress, represented by elevated thiobarbituric acid reactive substance (TBARS), nitric oxide and oxidative DNA damage, was ameliorated by *Phoenix dactylifera* seeds treatment. In addition, *Phoenix dactylifera* seeds restored the activities of hepatic antioxidant enzymes (superoxide dismutase and glutathione S-transferase) that were declined after CCl₄ treatment. Examination of liver histopathology revealed that *Phoenix dactylifera* seeds attenuate the incidence of liver lesions (including vacuolization and fibroblast proliferation) triggered by CCl₄ intoxication. Conclusion The *Phoenix dactylifera* seeds could be a promising candidate for protection against the CCl₄-induced liver intoxication, and this hepatoprotective effect might be attributed to the antioxidant and free radical scavenging activities. © 2014 Elsevier Ireland Ltd. Document Type: Article**Source:** ScopusAl-Saeed, T.A.^a, El-Zaiat, S.Y.^b**Modeling of vision loss due to vitreous hemorrhage by Monte Carlo simulation**(2014) *Journal of biomedical optics*, 19 (8), p. 085009.**DOI:** 10.1117/1.JBO.19.8.085009^a Helwan University, Faculty of Engineering, Biomedical Engineering Department, 1 Sherif Street, Helwan, 11792, Cairo, Egypt^b Ain-Shams University, Faculty of Science, Physics Department, Abbassia, 11566, Cairo, Egypt**Abstract**

Vitreous hemorrhage is the leaking of blood into the vitreous humor which results from different diseases. Vitreous hemorrhage leads to vision problems ranging from mild to severe cases in which blindness occurs. Since erythrocytes are the major scatterers in blood, we are modeling light propagation in vitreous humor with erythrocytes randomly distributed in it. We consider the total medium (vitreous humor plus erythrocytes) as a turbid medium and apply Monte Carlo simulation. Then, we calculate the parameters characterizing vision loss due to vitreous hemorrhage. This work shows that the increase of the volume fraction of erythrocytes results in a decrease of the total transmittance of the vitreous body and an increase in the radius of maximum transmittance, the width of the circular strip of bright area, and the radius of the shadow area.

The unsteady two-dimensional boundary layer stagnation-point flow of a nanofluid over a heated stretching sheet is investigated numerically. The unsteadiness in the flow, temperature and nanoparticle concentration fields is caused by the time-dependence of the stretching velocity, the free stream velocity and the surface temperature and concentration. The transport model employed includes the effects of Brownian motion, thermophoresis and time-dependent chemical reaction. The resulting non-linear governing equations with the associated boundary conditions are solved numerically using the shooting technique with the aid of similarity transformation. The velocity, temperature and nanoparticle volume fraction profiles, as well as the local Nusselt and Sherwood numbers, are analyzed due to the effect of the involved parameters of interest, namely the Brownian motion parameter Nb , thermophoresis parameter Nt , unsteadiness parameter S , velocity ratio parameter, chemical reaction parameter, Prandtl number and Lewis number Le . It is found that the mass transfer process at the solid-fluid interface is stopped for some values of Le , Nb , and Nt despite of the continuity of the heat transfer process for the same parameter values. © 2014 The Royal Swedish Academy of Sciences.

Abstract

A ring R with Jacobson radical J(R) is a homogeneous semilocal ring if R/J(R) is simple artinian. In this paper, we study the transfer of the property of being homogeneous semilocal from a ring R to the formal power series ring R[[x]], the skew formal power series ring R[[x, a]] and the Hurwitz series ring HR. The results of the paper generalize those proved for commutative local rings. We also consider finite centralizing extensions proving that if the ring of matrices Mn(R) is a homogeneous semilocal ring, then so is R. More generally, if e is an idempotent of a homogeneous semilocal ring S, then eSe is homogeneous semilocal. © World Scientific Publishing Company.

Abstract

Decolourization of reactive dyes wastewater supplemented with 1. mg/l cationic polymer (Organo Pol.) in a down flow hanging sponge (DHS) system was investigated at different HRTs and OLRs. The results obtained revealed that, increasing the HRT from 1.7 to 5. h, significantly increased the removal efficiencies of color and COD i.e. at a HRT of 5. h, and OLR not exceeding 2.8. g. COD/l. d, the reactor achieved removal efficiencies of $66.5 \pm 7.07\%$ for COD and $90.12 \pm 3.13\%$ for color. However, at longer HRT of 6.0. h, the decolorization process was substantially dropped, due to high salinity content in the influent. © 2013 The Korean Society of Industrial and Engineering Chemistry.

Abstract

An ecological and viable method for coating of cotton fabrics with silver nanoparticles (AgNPs) has been carried out. Nanocoated fabrics were characterized by scanning electron microscopy, energy dispersive X-ray and infrared spectroscopy. Color coordinates and silver release were assessed and the impact of repeated washings was evaluated. Silver contents were measured using atomic absorption spectroscopy and were 109.07 and 97.85 mg/kg for the fabrics treated with 100 ppm of AgNPs in presence and absence of binder respectively. Antibacterial activities of the cotton fabrics coated by AgNPs were evaluated qualitatively and quantitatively, and the results explored that, regardless of the concentration of AgNPs used, the biocidability was always higher without washing. However, for all coated fabrics, a sufficient antibacterial action still observed after 20 washings. The results revealed that valuable antibacterial textiles which are required in different medical textile fields could be successfully produced. © 2014 Elsevier Ltd.

What drives mandatory and voluntary risk reporting variations across Germany, UK and US?

(2014) *British Accounting Review*, . Article in Press.**DOI:** 10.1016/j.bar.2014.06.001^a The University of Bristol, UK^b The University of Stirling, UK^c The University of Plymouth, UK^d The University of Helwan, Egypt**Abstract**

This paper utilises computerised textual analysis to explore the extent to which both firm and country characteristics influence mandatory and voluntary risk reporting (MRR and VRR) variations both within and between non-financial firms across Germany, the UK and the US, over the period from 2005 to 2010. We find significant variations in MRR and VRR between firms across the three countries. Further, we find, on average, that German firms tend to disclose significantly higher (lower) levels of risk information mandatorily than UK (US) firms. German firms, on average, tend to reveal considerably higher (lower) levels of VRR than US (UK) firms. Our results document that MRR and VRR variations are significantly influenced by systematic risk, the legal system and cultural values. We also find that country and firm characteristics have higher explanatory power over the observed variations in MRR than over those in VRR. © 2014 Elsevier Ltd. All rights reserved.

Supra generalized closed soft sets with respect to an soft ideal in supra soft topological spaces

(2014) *Applied Mathematics and Information Sciences*, 8 (4), pp. 1731-1740.**DOI:** 10.12785/amis/080430^a Mathematics Department, Faculty of Science, Helwan University, Helwan, Egypt^b Mathematics Department, Faculty of Science, Zagazig University, Zagazig, Egypt^c Mathematics Department, Faculty of Education, Ain Shams University, Cairo, Egypt**Abstract**

The concept of soft ideal was first introduced by Kandil et al. [13]. In 1999, Molodtsov [22] introduced the concept of soft sets as a general mathematical tool for dealing with uncertain objects. The concept of generalized closed soft sets in soft topological spaces was introduced by Kannan [15] in 2012. The notions of supra soft topological space were first introduced by Kandil et al. [14]. In this paper, we introduce the concept of supra generalized closed soft sets(supra g-closed soft for short) in a supra topological space (X, μ, E) and study their properties in detail. Also, we introduce the

concept of supra generalized closed soft sets with respect to a soft ideal (supra- $\bar{I}g$ -closed soft for short) in a supra topological space (X, μ, E) and study their properties in detail, which is the extension of the concept of supra generalized closed soft sets. © 2014 NSP Natural Sciences Publishing Cor.

Abstract

The purpose of this paper is to introduce the notion of soft ideal in soft set theory. The concept of soft local function is also introduced. These concepts are discussed with a view to find new soft topologies from the original one. The basic structure, especially a basis for such generated soft topologies also studied here. Finally, the notion of compatibility of soft ideals with soft topologies is introduced and some equivalent conditions concerning this topic are established here. © 2014 NSP Natural Sciences Publishing Cor.

Abstract

Tuberculosis remains a major cause of mortality and morbidity, killing each year more than one million people. Although the combined use of first line antibiotics (isoniazid, rifampicin, pyrazinamide, and ethambutol) is efficient to treat most patients, the rapid emergence of multidrug resistant strains of *Mycobacterium tuberculosis* stresses the need for alternative therapies. Mycobacterial transcriptional repressor EthR is a key player in the control of second-line drugs bioactivation such as ethionamide and has been shown to impair the sensitivity of the human pathogen *Mycobacterium tuberculosis* to this antibiotic. As a way to identify new potent ligands of this protein, we have developed fragment-based approaches. In the current study, we combined surface plasmon resonance assay, X-ray crystallography, and ligand efficiency driven design for the rapid discovery and optimization of new chemotypes of EthR ligands starting from a fragment. The design, synthesis, and *in vitro* and *ex vivo* activities of these compounds will be discussed. © 2014 American Chemical Society.

Abstract

(3-(Naphthalen-1-yl)oxiran-2-yl)(5,6,7,8-tetrahydronaphthalen-2-yl)methanone was prepared and allowed to react with different nucleophile agents such as hydrazine hydrate, phenyl hydrazine, methyl hydrazine, and hydroxylamine hydrochloride to give hydroxy pyrazole 2 and hydroxy oxazole 3. Also, oxirane 1 reacted with semicarbazide and thiosemicarbazide to give substituted pyrazole 4a,b. Also, oxirane 1 was allowed to react with carbon disulfide, glycine, substituted isothiocyanate, and thiourea to give compounds 5-8, respectively. The thiopyrimidine derivative 8 was cyclized by chloroacetic acid or ethyl bromoacetate to give thiazolidine derivative 9, which condensed with different aldehydes to give compound 10a-c. Some of these newly synthesized compounds were evaluated as anticancer agents. © 2014 Springer Science+Business Media.

Abstract

We present evidence of optical Tamm states to surface plasmon polariton (SPP) coupling. We experimentally demonstrate that for a Bragg stack with a thin metal layer on the surface, hybrid Tamm-SPP modes may be excited when a grating on the air-metal interface is introduced. Out-coupling via the grating to free space propagation is shown to enhance the transmission as well as the directionality and polarization selection for the transmitted beam. We suggest that this system will be useful on those devices, where a metallic electrical contact as well as beaming and polarization control is needed. © 2014 AIP Publishing LLC.

Abstract

In cooperative Mobile Ad-hoc Networks (MANETs), copies of data are replicated on different mobile devices to improve system's availability. A primary or authoritative control node is assigned to act as a coordinator for the shared data copies, when this primary fails, another node has to be elected to replace the failed one. Since mobile devices have a limited battery power, the primary may fail at any time. Moreover, current primary election protocols in MANETs employ a notable wireless communication overhead which consumes a considerable amount of battery power. In this paper, we propose a novel protocol, called Primary Replacement Protocol (PRP), to replace an exhausted primary in MANETs based on the measurement of its remaining battery power early before it dies. More specifically, PRP replaces the exhausted primary with a healthy node when its remaining battery power reaches a predefined threshold. This replacement can be accomplished with much less communication overhead. Hence, our approach has two contributions: 1) reducing the chance of primary outage by early detection of potential power failure, 2) saving the power that is consumed in traditional primary election approaches due to communication overhead. © 2014, Springer Science+Business Media New York.

Abstract

The dual response surface methodology is one of the most commonly used approaches in robust parameter design to simultaneously optimize the mean value and keep the variance minimum. The commonly used meta-model is the quadratic polynomial regression. For highly nonlinear input/output relationship, the accuracy of the fitted model is limited. Many researchers recommended to use more complicated surrogate models. In this study, three surrogate

models will replace the second order polynomial regression, namely, ordinary Kriging, radial basis function approximation (RBF) and radial basis function artificial neural network (RBFNN). The results show that the three surrogate model present superior accuracy in comparison with the quadratic polynomial regression. The mean squared error (MSE) approach is widely used to link the mean and variance in one cost function. In this study, a new approach has been proposed using multi-objective optimization. The new approach has two main advantages over the classical method. First, the conflicting nature of the two objectives can be efficiently handled. Second, the decision maker will have a set of Pareto-front design points to select from. © 2014 Elsevier Inc. All rights reserved.

Abstract

In machine learning problems a learning algorithm tries to learn the input-output dependency (relationship) of a system from a training dataset. This input-output relationship is usually deformed by a random noise. From experience, simulations, and special case theories, most practitioners believe that increasing the size of the training set improves the performance of the learning algorithm. It is shown that this phenomenon is not true in general for any pair of a learning algorithm and a data distribution. In particular, it is proven that for certain distributions and learning algorithms, increasing the training set size may result in a worse performance and increasing the training set size infinitely may result in the worst performance - even when there is no model misspecification for the input-output relationship. Simulation results and analysis of real datasets are provided to support the mathematical argument. © 2013 Elsevier B.V. All rights reserved.

Effect of load angle on limit load of polyethylene miter pipe bends

(2014) *Journal of Pressure Vessel Technology, Transactions of the ASME*, 136 (3), art. no. 031202, . Cited 1 time.

DOI: 10.1115/1.4026069

Abstract

The aim of this paper is to investigate the effect of crack depth $a/W = 0-0.4$ and load angle (30 deg, 45 deg, and 60 deg) on the limit load of miter pipe bends (MPB) under out-of-plane bending moment with a crosshead speed 500 mm/min. The geometry of cracked and un-cracked multi miter pipe bends are: bend angle, $\alpha = 90$ deg, pipe bend factor, $h = 0.844$, standard dimension ratio, SDR = 11, and three junctions, $m = 3$. The material of the investigated pipe is a high-density polyethylene (HDPE), which is applied in natural gas piping systems. Butt-fusion welding is used to produce the welds in the miter pipe bends. An artificial crack is produced by a special cracking device. The crack is located at the crown side of the miter pipe bend, such that the crack is collinear with the direction of the applied load. The crack depth ratio, $a/W = 0, 0.1, 0.2, 0.3$, and 0.4 for out-of-plane bending moment "i.e., loading angle $\varphi = 0$ deg". For each out-of-plane bending moment and all closing and opening load angles the limit load is obtained by the tangent intersection method (TI) from the load deflection curves produced by the specially designed and constructed

testing machine at the laboratory (Mechanical Design Department, Faculty of Engineering, Mataria, Helwan University, Cairo/Egypt). For each out-of-plane bending moment case, the experimental results reveals that increasing crack depth leads to a decrease in the stiffness and limit load of MPB. In case of combined load (out-of-plane and in-plane opening; mode) higher load angles lead to an increase in the limit load. The highest limit load value appears at a loading angle equal, $\varphi = 60$ deg. In case of combined load (out-of-plane and in-plane closing; mode) the limit load decreases upon increasing the load angle. On the other hand, higher limit load values appear at a specific loading angle equal $\varphi = 30$ deg. For combined load opening case; higher values of limit load are obtained. Contrarily, lower values are obtained in the closing case. Copyright © 2014 by ASME.

Abstract

World energy demand is increasing at an alarming rate and producing electricity from alternative or renewable energy sources is becoming necessary. There are many technologies to extract electric energy from sea waves such as: the oscillating water column, the point absorber, the overtopping system and the bottom hinged system. Many researchers are focusing on modeling the floating point absorber, which is thought to be the most cost effective technology to extract energy from sea waves. This paper is mainly work on a new design of float and the analytical analysis of its performance. This float consists of two parts; a hollow cylinder and an inverted cup fixed to its bottom. The float is initially submerged in water with sufficient submergence float. Water rises up due to the wave action and the float will follow the water motion which reduces slamming of the float. When the water level drops, the water enclosed in the inverted cup is exposed to a negative pressure which help the float down to follow the water wave motion without slamming. In this work, an analytical model is used MATLAB SOFTWARE to simulate the system of energy conversion. Moreover, a comparison for this model of the simulation results with experimental data to validate the model. © 2014 Elsevier Ltd.

Abstract

Background: Pomegranate fruit has been extensively used as a natural medicine in many cultures. The present study was aimed at evaluating the protective effects of pomegranate (*Punica granatum*) juice against carbon tetrachloride (CCl₄)-induced oxidative stress and testes injury in adult Wistar rats. **Methods:** Twenty eight Wistar albino male rats were divided equally into 4 groups for the assessment of protective potential of pomegranate juice. Rats of group I (control) received only vehicles and had free access to food and water. Rats of groups II and IV were treated with CCl₄ (2 ml/kg bwt) via the intraperitoneal route once a week for ten weeks. The pomegranate juice was supplemented via drinking water 2 weeks before and concurrent with CCl₄ treatment to group IV. Group III was supplemented with

pomegranate juice for twelve weeks. The protective effects of pomegranate on serum sex hormones, oxidative markers, activities of antioxidant enzymes and histopathology of testes were determined in CCl₄-induced reproductive toxicity in rats. **Results:** Pomegranate juice showed significant elevation in testosterone, luteinizing hormone (LH) and follicle stimulating hormone (FSH) those depleted by the injection of CCl₄. Activity levels of endogenous testicular antioxidant enzymes; superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx), glutathione-S-transferase (GST) and glutathione reductase (GR) and glutathione (GSH) contents were increased while lipid peroxidation (LPO) and nitric oxide (NO) were decreased with pomegranate juice. Moreover, degeneration of germ and Leydig cells along with deformities in spermatogenesis induced after CCl₄ injections were restored with the treatment of pomegranate juice. **Conclusion:** The results clearly demonstrated that pomegranate juice augments the antioxidant defense mechanism against carbon tetrachloride-induced reproductive toxicity and provides evidence that it may have a therapeutic role in free radical mediated diseases. © 2014 Al-Olayan et al.; licensee BioMed Central Ltd.

Abstract

Heartbeat measurement is important in assessing cardiac function because variations in heart rhythm can be the cause as well as an effect of hidden pathological heart conditions. Zebrafish (*Danio rerio*) has emerged as one of the most useful model organisms for cardiac research. Indeed, the zebrafish heart is easily accessible for optical analyses without conducting invasive procedures and shows anatomical similarity to the human heart. In this study, we present a non-invasive, simple, cost-effective process to quantify the heartbeat in embryonic zebrafish. To achieve reproducibility, high throughput and flexibility (i.e., adaptability to any existing confocal microscope system and with a user-friendly interface that can be easily used by researchers), we implemented this method within a software program. We show here that this platform, called ZebraBeat, can successfully detect heart rate variations in embryonic zebrafish at various developmental stages, and it can record cardiac rate fluctuations induced by factors such as temperature and genetic- and chemical-induced alterations. Applications of this methodology may include the screening of chemical libraries affecting heart rhythm and the identification of heart rhythm variations in mutants from large-scale forward genetic screens.

Abstract

Using bicolor laser treatment by Nd:YAG 20 ns laser (1064-532 nm) and 180 ns CO₂ laser beams (10.6-5.3 μm) it was shown a possibility of critical temperature enhancement in ferromagnetic superconducting MgB₂/CrO₂ bilayer films. The role of the phonon sub-system effectively interacting with 3d Cr originating localized trapping levels is discussed. The pump-probe laser kinetics for the probing second harmonic generation at 1064 nm is explored in details to show principal role of the localized trapping levels. The relaxation of the processes after the switching off the photo inducing beams show the disappearance of the enhanced superconductivity after the 20-30 s. The temperature dependence of the resistance show nonlinear dependence versus the pumping power and different optimal fundamental to writing power density beams ratio. © 2014 Elsevier B.V. Abstract

Flame development, propagation, stability, combustion efficiency, pollution formation, and overall system efficiency are affected by the early stage of flame generation defined as flame kernel. Studying the effects of turbulence and chemistry on the flame kernel propagation is the main aim of this work for natural gas (NG) and liquid petroleum gas (LPG). In addition the minimum ignition laser energy (MILE) has been investigated for both fuels. Moreover, the flame stability maps for both fuels are also investigated and analyzed. The flame kernels are generated using Nd:YAG pulsed laser and propagated in a partially premixed turbulent jet. The flow field is measured using 2-D PIV technique. Five cases have been selected for each fuel covering different values of Reynolds number within a range of 6100-14400, at a mean equivalence ratio of 2 and a certain level of partial premixing. The MILE increases by increasing the equivalence ratio. Near stoichiometric the energy density is independent on the jet velocity while in rich conditions it increases by increasing the jet velocity. The stability curves show four distinct regions as lifted, attached, blowout, and a fourth region either an attached flame if ignition occurs near the nozzle or lifted if ignition occurs downstream. LPG flames are more stable than NG flames. This is consistent with the higher values of the laminar flame speed of LPG. The flame kernel propagation speed is affected by both turbulence and chemistry. However, at low turbulence level chemistry effects are more pronounced while at high turbulence level the turbulence becomes dominant. LPG flame kernels propagate faster than those for NG flame. In addition, flame kernel extinguished faster in LPG fuel as compared to NG fuel. The propagation speed is likely to be consistent with the local mean equivalence ratio and its corresponding laminar flame speed. Copyright © Taylor & Francis Group, LLC.

Abstract

In recent years, an amplified global awareness has led to a reawakening of interest in renewable energy technology. In an effort to reduce the worldwide dependence on fossil fuels, cleaner power generation methods are being sought in the field of solar, biomass, wind and wave energy. The importance of wave energy is increased in particular in some countries like UK, Portugal, Spain and Japan. A considerable progress has already been achieved in this field but the available technical designs are not adequate to develop reliable wave energy converters. Wave energy is the most available energy associated in water seas and oceans. Simultaneously, the wave energy has consisted of two types of energies: potential and kinetic energy. Therefore, many attempts have been applied to capture these energies. In the present work, a wave generator device has been designed and manufactured to simulate and generate the heaving motion of sea waves with different specification. A PC based electro-pneumatic control system was designed and implemented to individually control wave height, these heights are 3, 8, 16, 18 and 20cm and different frequencies to generate these regular and irregular waves. © 2014 Elsevier Ltd.

Abstract

The Additive Manufacturing (AM) process is a computer-controlled process that uses CAD representations to build physical parts layer by layer. Almost all computer-aided design (CAD) packages allow the creation of stereolithography (STL) files, which are translated into machine commands to drive the AM process. Unfortunately, the STL file has many weaknesses and is prone to error. Moreover, there is a need to investigate and understand the issues and errors associated with the software formats and how to control, eliminate, or minimize these errors. Failure to deal with these issues will lead to building poor parts and delayed lead time, which will result in a bad physical model. This chapter summarizes the CAD model of the AM process and explains the various software issues related to the selected CAD representation. © 2014 Elsevier Ltd All rights reserved.

Effects study of Nigella Sativa, its Oil and their combination with Vitamin E on oxidative stress in rats

(2014) *American Journal of Applied Sciences*, 11 (7), pp. 1079-1086.

DOI: 10.3844/ajassp.2014.1079.1086

Department of Nutrition and Food Sciences, Helwan University, Cairo, Egypt

Abstract

Antioxidants or free radical scavengers are very important in protecting the living cells against any damage induced by free radicals. The effects of Nigella Sativa Extract (NSE), Nigella Sativa Oil (NSO) and Vitamin E (Vit. E) and the combination of NSE or NSO with Vit. E on potassium bromate (KBrO₃)-induced oxidative stress in male rats were investigated. Forty nine Sprague Dawley male rats were weighing 185±5 g and 10-12 weeks old were used to achieve the present study. According to the results, oral administration of NSE or NSO alone and in combination with vitamin E exhibited weight gain and feed efficiency ratio and lowered the elevated serum levels of total cholesterol, triglycerides, AST, ALT, urea nitrogen, uric acid and creatinine. Further, they lowered malondialdehyde and increased the reduction in glutathione content and activities of antioxidant enzymes (GPx, SOD and CAT) in liver tissues. Collectively, these results indicate that dietary intake of NSE or NSO alone and in combination with Vitamin E could

be a potential therapeutic in the treatment of related diseases with oxidative stress. ©2014 Science Publication.

^c Chemistry Department, Helwan University, Helwan, Cairo 11727, Egypt

Abstract

This work presents a new method to prepare monodisperse magnetite nanoparticles capping with new cationic surfactants based on rosin. Core/shell type magnetite nanoparticles were synthesized using bis-N-(3-levopimamic maleic acid adduct-2-hydroxy) propyl-triethyl ammonium chloride (LPMQA) as capping agent. Fourier transform infrared spectroscopy (FTIR) was employed to characterize the nanoparticles chemical structure. Transmittance electron microscopies (TEM) and X-ray powder diffraction (XRD) were used to examine the morphology of the modified magnetite nanoparticles. The magnetite dispersed aqueous acid solution was evaluated as an effective anticorrosion behavior of a hydrophobic surface on steel. The inhibition effect of magnetite nanoparticles on steel corrosion in 1 M HCl solution was investigated using potentiodynamic polarization curves and electrochemical impedance spectroscopy (EIS). Results obtained from both potentiodynamic polarisation and EIS measurements reveal that the magnetite nanoparticle is an effective inhibitor for the corrosion of steel in 1.0 M HCl solution. Polarization data show that magnetite nanoparticles behave as a mixed type inhibitor. The inhibition efficiencies obtained from potentiodynamic polarization and EIS methods are in good agreement. © 2014 by the authors; licensee MDPI, Basel, Switzerland.

Abstract

Caspase-1 activation is a central event in innate immune responses to many pathogenic infections and tissue damage. The NLRP3 inflammasome, a multiprotein scaffolding complex that assembles in response to two distinct steps, priming and activation, is required for caspase-1 activation. However, the detailed mechanisms of these steps remain poorly characterized. To investigate the process of LPS-mediated NLRP3 inflammasome priming, we used constitutively present pro-IL-18 as the caspase-1-specific substrate to allow study of the early events. We analyzed human monocyte caspase-1 activity in response to LPS priming, followed by activation with ATP. Within minutes of endotoxin priming, the NLRP3 inflammasome is licensed for ATP-induced release of processed IL-18, apoptosis-associated speck-forming complex containing CARD, and active caspase-1, independent of new mRNA or protein synthesis. Moreover, extracellular signal-regulated kinase 1 (ERK1) phosphorylation is central to the priming process. ERK inhibition and small interfering RNA-mediated ERK1 knockdown profoundly impair priming. In addition, proteasome inhibition prevents ERK phosphorylation and blocks priming. Scavenging reactive oxygen species with

diphenylene iodonium also blocks both priming and ERK phosphorylation. These findings suggest that ERK1-mediated posttranslational modifications license the NLRP3 inflammasome to respond to the second signal ATP by inducing posttranslational events that are independent of new production of pro-IL-1 β and NOD-like receptor components. Abstract

Drug resistance is a major impediment for cancer treatment, to overcome it we designed and synthesized sixteen coumarins bearing hydrazide-hydrazone moiety and evaluated them against human drug-resistant pancreatic carcinoma (Panc-1) cells and drug-sensitive (hepatic carcinoma; Hep-G2 and leukemia; CCRF) cell lines in vitro. The 6-brominated coumarin hydrazide-hydrazone derivatives (BCHHD) 7c, 8c and 10c were more potent than doxorubicin (DOX) against resistant Panc-1 cells. BCHHD 7c showed significant cytotoxicity against all tested cells (IC₅₀: 3.60-6.50 μ M) on comparison with all other coumarin hydrazide-hydrazone derivatives (CHHD), whereas BCHHD's 8c and 10c showed significant antiproliferative activity only against resistant Panc-1 cells with IC₅₀ of 2.02 μ M and 2.15 μ M, respectively. All the investigated BCHHD's were able to activate caspases 3/7 and they could induce apoptosis in resistant Panc-1 cells. Microarray analysis showed that BCHHD 7c induced the expression of apoptotic- and cell cycle arrest (G₂/M)- genes in resistant Panc-1 cells. Moreover, BCHHD 7c induced the up-regulation of CDKN1A, DDIT4, GDF-15 and down-regulation of CDC2, CDC20, CDK2 genes. Based on our results, we conclude that 7c could be a potent anticancer drug to overcome drug resistance in cancer and it could be highly beneficial for patients in the clinic. © 2014 Elsevier Masson SAS. Abstract

Four simple, accurate, reproducible, and selective methods have been developed and subsequently validated for the determination of Benazepril (BENZ) alone and in combination with Amlodipine (AML) in pharmaceutical dosage form. The first method is pH induced difference spectrophotometry, where BENZ can be measured in presence of AML as it showed maximum absorption at 237 nm and 241 nm in 0.1 N HCl and 0.1 N NaOH, respectively, while AML has no wavelength shift in both solvents. The second method is the new Extended Ratio Subtraction Method (EXRSM) coupled to Ratio Subtraction Method (RSM) for determination of both drugs in commercial dosage form. The third and fourth methods are multivariate calibration which include Principal Component Regression (PCR) and Partial Least Squares (PLSs). A detailed validation of the methods was performed following the ICH guidelines and the standard curves were found to be linear in the range of 2-30 μ g/mL for BENZ in difference and extended ratio subtraction spectrophotometric method, and 5-30 for AML in EXRSM method, with well accepted mean correlation coefficient for each analyte. The intra-day and inter-day precision and accuracy results were well within the acceptable limits. ©

Abstract

Aqueous dispersions of nano-scale organic pigments were prepared through ball milling and ultra-sonication in presence of dispersing agents. The well dispersed pigment was encapsulated into UV-curable resin via miniemulsion technique. Effects of molecular structure of organic pigments, type of dispersing agent and time of ball milling were investigated. Results showed that C.I. Pigment Green 7 had better dispersion stability with time compared with other pigments. Ultracentrifuge sedimentation test, shelf life stability, thermal gravimetric analysis (TGA) and transmission electron microscope (TEM) provided supporting evidences for the encapsulation of C.I. Pigment Green 7 into polyester tetra acrylate/1,6-hexandiol dimethacrylate. Zeta potential results proved that UV-curable encapsulation of C.I. Pigment Green 7 intensifies the charge on the surface of the pigment and significantly increases the dispersion stability. This method of modifying organic pigments to be used as pigmented UV-curable inkjet inks was found to be durable and effective in preliminary application in inkjet printing of textiles. © 2014 Elsevier B.V.

Numerical optimization of axial turbine with self-pitch-controlled blades used for wave energy conversion

(2014) *International Journal of Energy Research*, 38 (5), pp. 592-601. Cited 1 time.

DOI: 10.1002/er.3064

Mechanical Power Engineering Department, Faculty of Engineering-Mattaria, Helwan University, Cairo, Egypt

Abstract

Wells turbines are among the most practical wave energy converters despite their low aerodynamic efficiency and power produced. It is proposed to improve the performance of Wells turbines by optimizing the blade pitch angle. Optimization is implemented using a fully automated optimization algorithm. Two different airfoil geometries are numerically investigated: the standard NACA 0021 and an airfoil with an optimized profile. Numerical results show that each airfoil has its own optimum blade pitch angle. The present computational fluid dynamics optimization results show that the optimum blade pitch angle for NACA 0021 is +0.3° while that of the airfoil with an optimized profile equals +0.6°. The performance of the investigated airfoils is substantially improved by setting the blades at the optimum blade pitch angle. Both the turbine efficiency and tangential force coefficient are improved, especially at low flow rate and during turbine startup. Up to 4.3% average increase in turbine efficiency is achieved by optimizing the blade pitch angle. A slight improvement of the tangential force coefficient and decrease of the axial force coefficient are also obtained. A tangible increase of the stall-free operating range is also achieved by optimizing the blade pitch angle. © 2013 John Wiley & Sons, Ltd.

New forensic ENF reference database for media recording authentication based on harmony search technique

using gis and wide area frequency measurements(2014) *IEEE Transactions on Information Forensics and Security*, 9 (4), art. no. 6732893, pp. 633-644.**DOI:** 10.1109/TIFS.2014.2304838^a Electronics, Computer Engineering Department, Helwan University, Cairo 11792, Egypt^b Electrical Power and Machines Engineering Department, Helwan University, Cairo 11792, Egypt**Abstract**

In forensic sciences, verification of digital media recordings is an important aspect. Electrical network frequency (ENF) criterion is a promising technique for media recording authentication. The ENF reference database is recorded from a single point on the power grid based on the fact that the ENF variation is the same across all points on the grid. This fact is not valid in case of system disturbances, whereas the ENF as a reference database varies in time and space. Post-disturbance ENF recorded from a single point is mismatched with the ENF extracted from media recorded at any other point on the grid. This will lead to judicial errors in the forensic examination of recordings. A new method for establishing a robust ENF reference database using geographical information system (GIS) and wide area frequency measurements is proposed. The method is based on building the ENF reference database from a number of frequency sensors deployed over multipoint on the grid rather than single point. The minimum number of sensors required is determined according to the frequency sensitivity of the ENF extraction algorithm and the estimation accuracy of the frequency sensor. The sensors locations are decided based on partitioning the power grid to a set of geographical frequency coherent areas. A novel harmony search algorithm using GIS data and wide area frequency measurements is proposed to identify the geographical frequency coherent areas for different disturbance scenarios. Results showed that the proposed method can be used to enhance the accuracy of the ENF database matching process. © 2005-2012 IEEE.

In this letter, we present a new formula for the resonance wavelength of an integrated optical ring resonator with small radius of curvature. Our formula is based on the expansion of the guide effective index as a function of the wavelength and then solving the resonance equation for the extraction of the resonance wavelength and free spectral range. The obtained results are compared with the finite difference time domain results and very good agreement is obtained. Using this new formula, we showed that the error in the resonance wavelength is reduced more than an order of magnitude from ~5.73% to be below 0.45%. © 2014 IEEE.

Cited 4 times.**DOI:** 10.1016/j.supflu.2014.01.015^a Dpto. de Química Física i, Universidad Complutense, E-28040 Madrid, Spain^b Chemistry Department, Faculty of Science, Helwan University, El Cairo, Egypt**Abstract**

Dissolution rate enhancement of the anti-inflammatory drug diflunisal was achieved using for the first time a supercritical fluid technology. The supercritical fluid antisolvent (SAS) method was applied to precipitate diflunisal alone and to coprecipitate the drug together with the biocompatible polymer polyvinylpyrrolidone (PVP K-30 and K-10). The untreated and SAS processed diflunisal, and the coprecipitates were characterized in terms of size, morphology, crystallinity, compositions, drug-polymer interactions, and drug release. SAS processed diflunisal exhibited a polymorphic form different from that of the untreated drug. Diflunisal crystallinity disappeared in the coprecipitates. Three different drug: polymer mass ratios were studied: 75:25, 50:50, and 25:75. Microparticle size decreased and aggregation disappeared as the relative amount of polymer increased. The 25:75 coprecipitate consisted of loose spherical particles exhibiting mean particle size of 410 nm while the 75:25 coprecipitate consisted of bigger aggregated particles. The SAS method was shown to be a suitable technology to form solid dispersions of a poorly soluble drug. © 2014 Elsevier B.V.

Cited 1 time.**DOI:** 10.1016/j.radphyschem.2013.10.007^a Physics Department, Faculty of Science, King Abdulaziz University, North Jeddah, Saudi Arabia^b Physics Department, Girls Faculty of Science, King Abdulaziz University, Jeddah, Saudi Arabia^c Physics Department, University College, Umm Al-Qura University, Makka, Saudi Arabia^d Physics Department, Faculty of Science, Helwan University, Cairo, Egypt**Abstract**

The natural radiation levels in soil and sediment samples collected from floating water from a land runway resulting from heavy rains in the Jeddah region as well as the activity in the population of its surrounding environments were studied. In the regions surrounding Jeddah, the movements of floating water may increase the concentration of radioactivity due to the movement of soil due to heavy rains. In addition, the technological development of industry, agriculture and other sources around the Jeddah region has increased environmental pollution, resulting in noticeable concentrations of radioactivity. The measured activity concentrations of ^{214}Pb , ^{214}Bi , ^{228}Ac , ^{208}Ti , ^{40}K , ^{226}Ra and ^{228}Ra in the studied area suggest that they are within the world average for soils and sediments, except those for water sample no. 4; the concentration in this sample was five times higher than the world average concentration (this water is not consumable). Herein, the radioactivity concentrations that were obtained from the analysis of soil and sediment samples that were collected from the investigated area are discussed. Additionally, the absorbed dose rate (D), radium equivalent activity (Raeq), external hazard index (Hex), annual gonadal dose equivalent (AGDE) and annual effective dose equivalent (AEDE) were evaluated. For the soil and sediment samples, the average radioactivity concentrations were determined for each site and are expressed in Becquerels per kilogram (Bq/kg) of dry weight, while for the measurement of both the ^{226}Ra and ^{228}Ra isotopes in the water samples, the activity concentration is expressed in picoCuries per liter (pCi/l). The obtained results were compared with other measurements from different countries. The movement of floating water around the Jeddah region increases the concentration of radioactivity due to the movement of soils with heavy rains. © 2013 Elsevier Ltd.

(2014) *Pigment and Resin Technology*, 43 (2), art. no. 17105903, pp. 84-91.**DOI:** 10.1108/PRT-12-2012-0090^a Polymers and Pigments Department, National Research Centre, Cairo, Egypt^b Textile Research Division, National Research Centre, Cairo, Egypt^c Chemistry Department, Faculty of Science, Ain Shams University, Cairo, Egypt^d Faculty of Applied Arts, Helwan University, Cairo, Egypt**Abstract**

Purpose - The purpose of this paper is to prepare nano size micro-emulsion co-polymer particles based on butyl acrylate (BA)/acrylic acid (AAc) with high monomer/surfactant ratio. The study involved the application of the prepared micro-emulsions co-polymers as textile pigment printing binders. Design/methodology/approach - The micro-emulsion co-polymerisations processes were carried out with different mixtures of BA and AAc using modified process. Sodium dodecyl sulphate (SDS) and potassium peroxy disulphate/glucose were used as emulsifier and redox initiator, respectively. The prepared emulsion co-polymer was characterized via spectroscopic measurements, FT-IR, δ -H-NMR and transmission electron microscope (TEM), in addition to thermal analysis. The prepared micro-emulsion co-polymers were applied as binders for pigment printing process onto cotton fabric, polyester and cotton/polyester blend by using flat screen technique. The optimum curing conditions were determined, colour strength and fastness properties of pigment printed areas to light, washing, perspiration and rubbing were evaluated. In addition, stiffness of the prints was studied. Findings - The achieved results indicated that particle size and homogeneity of the prepared micro-emulsions depend on monomers weight ratio, initiator and emulsifier concentrations. On the other hand, the prints obtained using the prepared binders with optimum conditions have satisfactory fastness, good handle and high colour yield. Research limitations/implications - Monomers were continuously and slowly added into the polymerising system with mild stirring to avoid disturbing the stability of the micro-emulsion. Also, emulsifier and initiator concentrations should be controlled to avoid coagulation. Practical implications - The research provides textile pigment printing binder with nano particle size within the range of 24-48 nm. Using the prepared nano binders in pigment printing enhances the stiffness, handle, and fastnesses properties of the prints. Originality/value - The prepared co-polymer binders showed high-performance physico-mechanical properties; in addition, the ultimate goal of this study is to prepare a nano size binder with high monomer/surfactant ratio using a modified micro-emulsion process. The offshore Nile Delta Basin, Egypt, has been known for a long time as a significant source of gas and oil. The study area is located on the Middle Eastern part of the Nile Delta near Mansoura City. The magnetotelluric method (MT) has emerged as a promising tool for oil exploration than any other geophysical technique. Hydrocarbon reservoirs typically exhibit higher electromagnetic resistivity than their surroundings. In this paper, the MT method was used to investigate the resistivity subsurface structure that related to hydrocarbon exploration, and the results were integrated with seismic data collected in the same area. The MT survey was performed using two frequency ranges: high (10 Hz to 100 kHz) and low (0.1 Hz to 1 kHz). Low-frequency natural MT waves were recorded using AMT only, and the measurement was then repeated using an artificial signal source for CSAMT. These surveys were carried out along three profiles having 22 sites. The recorded time-series data were transformed to the frequency domain and

processed to determine apparent resistivities and phases at each site in which the determinant average of the impedance tensor was then used for 1D and 2D inversion. A good coherence was found between the electromagnetic and seismic profiles and shows that the hydrocarbon is exiting in the Abu Madi and Qawasim channel which represent the main gas-containing layers in the Nile Delta. The depth and extension of these layers were estimated and imaged with a maximum thickness of 4,000 m at profile 1 in the northwestern part of the study area. © 2014, Saudi Society for Geosciences.

Wind turbine planetary gearbox health diagnostic using time-varying meshing stiffness

(2014) *Australian Journal of Mechanical Engineering*, 12 (1), pp. 1-12.

Helwan University, Cairo, Egypt

Abstract

In wind turbine planetary gearbox, the ability to identify ring-planet-sun gears meshing stiffness from the real data of vibration responses makes it possible to determine the physical existed planet gear defects which are used for severity assessments. There are limitations for vibration based gear diagnostic methods. Vibrations are secondary effects in the sense that they are dynamic responses of a gearbox excited by meshing stiffness and other excitations. The aim of this work is to diagnose the level of defects (gear tooth crack, gear tooth spalling and gear tooth breakage) in wind turbine gearbox using gears meshing stiffness. Time-varying meshing stiffness is used, where, a technique consists of a non-linear numerical optimisation is applied. The optimisation uses a dynamic model of the gears mesh and forms an estimate of both time-varying and frequency-varying mesh stiffness that best corresponds to the given set of vibration data. Multi-hour tests were conducted and recordings were acquired using translation vibration monitoring, where the optimum meshing stiffness was computed. The optimum meshing stiffness with the recording time was highlighted suggesting critical changes in the operation of the gearbox. The results indicate that if one tooth is defected due to cracks, spalling and breakage to reach the setting maximum level, the maintenance regime will be called despite a new damage is prone in the adjacent tooth to save time and cost. © Institution of Engineers Australia, 2014.

Abstract

The atomic structures of SrTiO₃ (STO)/LaNiO₃ (LNO)/STO heterostructure interfaces were investigated by spherical aberration-corrected (CS) (scanning) transmission electron microscopy. Atomic displacement and lattice distortion measurements and electron energy loss spectroscopy (EELS) were used to quantitatively analyze the distortion of the interfacial octahedra and the bond length at the interfaces. Combined with high-resolution transmission electron microscopy (HRTEM) and scanning transmission electron microscopy analyses, two distinct interfacial atomic terminating layers are unambiguously determined. Ensuing quantitative HRTEM measurements revealed that the Ni-O bond length in the interfacial octahedral is elongated at the bottom interface (-NiO₂-SrO-). Atomic displacement shows structural relaxation effects when crossing the interfaces and lattice distortions across the interface is more pronounced in LNO than in STO. The Ti/O atomic ratio, La and Ti relative atomic ratio as derived by EELS quantification indicate non-stoichiometric composition at the interfaces. Distinct fine structures of Ti-L2,3 edge and O-K edge at the bottom and top interfaces are observed. By comparison, we are able to estimate Ti valency at both

interfaces. Combining the structural distortions and Ti valency, the polar discontinuity and charge transfer at the interfaces are discussed. © 2014 AIP Publishing LLC.

Abstract

Two series of chalcone and thiopyrimidine benzofuran derivatives were designed, synthesized and evaluated in vitro for their vascular endothelial growth factor receptor (VEGFR-2) inhibitory activity, their cytotoxicity on seventeen human cancer cell lines and their in vivo antiprostate cancer activity. The highest anti-VEGFR-2 activity was demonstrated by 1-(6-hydroxy-4-methoxybenzofuran-5-yl)-3-(4-nitrophenyl)prop-2-en-1-one (6d) exhibiting an IC₅₀ value (1.00×10^{-3} μM) higher than the reference drug Sorafenib (IC₅₀ = 2.00×10^{-3} μM). On the other hand, most of the synthesized compounds showed potent cytotoxicity against most of the tested cell lines and were more potent than the reference drugs, in particular, bromovisnagin (4) exhibited the best activity on the majority of the cell lines with IC₅₀ values ranging from 3.67×10^{-13} to 7.65×10^{-7} μM. Moreover, the synthesized compounds showed significant in vivo antiprostate cancer activity. The docking experiments were performed using the GOLD program on (VEGFR-2) kinase which introduced new information about the enzyme-inhibitor interaction and the potential therapeutic application of the benzofuran scaffold. © The Royal Society of Chemistry 2014.
